About this documentation

This documentation describes how to install, configure, use, and extend Open Beta for Zowe.

Who should read this documentation

This documentation is intended for system programmers who are responsible for installing and configuring Zowe, application developers who want to use Zowe to improve z/OS user experience, and anyone who wants to understand how Zowe works or is interested in extending Zowe to add their own plug-ins or applications.

The information provided assumes that you are familiar with the mainframe and z/OSMF configuration.

How to send your feedback on this documentation

We value your feedback. If you have comments about this documentation, you can use one of the following ways to provide feedback:

- Send a GitHub pull request to provide a suggested edit for the content by clicking the **Propose content change in GitHub** link on each documentation page.
- Open an issue in GitHub to request documentation to be updated, improved, or clarified by providing a comment.

Sending a GitHub pull request

You can provide suggested edit to any documentation page by using the **Propose content change in GitHub** link on each page. After you make the changes, you submit updates in a pull request for the Zowe content team to review and merge.

Follow these steps:

1. Click **Propose content change in GitHub** on the page that you want to update.
2. Click the **Edit the file** icon .
3. Make the changes to the file.
4. Scroll to the end of the page and enter a brief description about your change.
5. Optional: Enter an extended description.
6. Select **Propose file change**.
7. Select **Create pull request**.

Opening an issue for the documentation

You can request the documentation to be improved or clarified, report an error, or submit suggestions and ideas by opening an issue in GitHub for the Zowe content team to address. The content team tracks the issues and works to address your feedback.

Follow these steps:

1. Click the **GitHub** link at the top of the page.
2. Select **Issues**.
3. Click **New issue**.
4. Enter a title and description for the issue.
5. Click **Submit new issue**.

Release notes for Open Beta

Learn about what is new, changed, removed, and known issues in Open Beta for Zowe.

Zowe Open Beta includes the following releases:

- [Version 0.9.2 \(October 2018\)](#)
- [Version 0.9.1 \(October 2018\)](#)
- [Version 0.9.0 \(August 2018\)](#)

Version 0.9.2 (October 2018)

Version 0.9.2 contains the following changes since the last version.

What's new

New in Zowe CLI

The Visual Studio Code (VSCode) Extension for Zowe is now available. Using the extension you can data sets, view their contents, make changes, and upload the changes to the mainframe directly from the Visual Studio Code user interface. You install the extension directly to Visual Studio Code to enable the extension within the UI. For more information, see [VSCode Extension for Zowe](#).

What's changed

Changed in Explorer Server

- The URLs to access the explorer server UI are changed.

URL in 0.9.1	URL in 0.9.2
<code>https://<your.server>:<atlasport>/explorer-jes/#/</code>	<code>https://<your.server>:<atlasport>/ui/v1/jobs/#/</code>
<code>https://<your.server>:<atlasport>/explorer-mvs/#/</code>	<code>https://<your.server>:<atlasport>/ui/v1/datasets/#/</code>
<code>https://<your.server>:<atlasport>/explorer-uss/#/</code>	<code>https://<your.server>:<atlasport>/ui/v1/uss/#/</code>

- All explorer server REST APIs are changed. The `/Atlas/api/` portion of an explorer server REST API is changed to `/api/v1/`. For example, `GET /Atlas/api/datasets/{filter}` is changed to `GET /api/v1/datasets/{filter}`.

For a list of the new APIs, see [Using APIs](#).

Changed in Zowe CLI

This version of Zowe CLI contains the following changes:

- Zowe CLI no longer uses keytar to store credentials securely in your operating system's credential vault. The user names and passwords that are stored in zosmf profiles and other profile types are now stored in plain text. When you update from a previous version of Zowe CLI, and your credentials are stored securely, you must update, or optionally, re-create your profiles.

Important! Use the following steps only if you were using a version of Zowe CLI that is older than version 0.9.2.

Follow these steps: 1. Issue any `bright` command to create the `~/ .zowe` home directory. 2. After you create the directory, copy the complete contents of the `~/ .brightside` directory to the newly created `~/ .zowe` directory. Copying the contents of the `~/ .brightside` directory to the `~/ .zowe` directory restores the profiles you created previously. 3. To help ensure that your plug-ins function properly, reinstall the plug-ins that you installed with older versions of Zowe CLI. 4. After you migrate your profiles, issue the following command to list your existing profiles: `bright profiles list zosmf` 5. Update each profile for compatibility with the credential storage changes by issuing the following command: `bright profiles update zosmf <profilename> -u <username> -p <password>` 6. (Optional) If you do not want to migrate your profiles from `~/ .brightside` to `~/ .zowe` you can recreate your profiles using the following command: `bright profiles create zosmf`

****Tip:**** For more information, see [Create a Zowe CLI profile](cli-installcli.md#creating-a-zowe-cli-profile).

Note: In future versions of Zowe CLI, plug-ins will be available that let you store your user credentials securely, which is similar to the previous behavior.

- As mentioned in the previous bullet, Zowe CLI no longer uses keytar to store credentials securely in your operating system's credential vault. As a result, Zowe CLI requires only **Node.js** and **npm** as prerequisite software. For more information, see [System Requirements for Zowe CLI](#).

Version 0.9.1 (October 2018)

Version 0.9.1 contains the following changes since the last version.

What's new

New in the Zowe Application Framework

The Workflows application plug-in was added to the Zowe Application Framework (zLUX).

The API Catalog plug-in was added to the Zowe Application Framework. This plug-in lets you view API services that have been discovered by the API Mediation Layer.

Angular application plug-ins can be internationalized utilizing the `ngx-i18n` library.

The Zowe Application Framework now provides a sample react app, Angular app, and a sample editor.

The following tutorials are now available in GitHub:

Sample React app: [sample-react-app](#)

Sample Angular app: [sample-angular-app](#)

Internationalization in Angular Templates in Zowe zLUX

[sample-angular-app \(Internationalization\)](#)

App to app communication

[sample-angular-app \(App to app communication\)](#)

Using the Widgets Library

[sample-angular-app \(Widgets\)](#)

Configuring user preferences (configuration dataservice)

[sample-angular-app \(configuration dataservice\)](#)

New in Zowe CLI

Zowe CLI contains the following new features:

- **Zowe CLI Plug-in for IBM® CICS®**

The new plug-in lets you extend Zowe CLI to interact with CICS programs and transactions. It uses the IBM CICS Management Client Interface (CMCI) API to achieve the interaction with CICS.

As an application developer, you can use the plug-in to perform various CICS-related tasks, such as the following:

- Deploy code changes to CICS applications that were developed with COBOL.
- Deploy changes to CICS regions for testing or delivery.
- Automate CICS interaction steps in your CI/CD pipeline with Jenkins Automation Server or TravisCI.

For more information, see [Zowe CLI Plug-in for IBM CICS](#).

• **zos-jobs and zos-files commands and command options**

Zowe CLI contains the following new commands and command options:

- `zowe zos-jobs delete job` command: Lets you cancel a job and purge its output by providing the JOB ID.
- `zowe zos-files upload file-to-uss` command: Lets you upload a local file to a file on USS.
- `zowe zos-files download uss-file` command: Lets you download a file on USS to a local file.
- `zowe zos-jobs submit local-file` command: Lets you submit a job contained in a local file on your PC rather than a data set.
- `zowe zos-jobs download output` command: Lets you download the complete spool output for a job to a local directory on your PC.
- The `zowe zos-jobs submit data-set` command and the `zowe zos-jobs submit local-file` command now contain a `--view-all-spool-content` option. The option lets you submit a job and view its complete spool output in one command.

• **Visual Studio Code Extension for Zowe**

The Visual Studio Code (VSCode) Extension for Zowe is now available. You can install the extension directly to Visual Studio Code to enable the extension within the UI. Using the extension you can data sets, view their contents, make changes, and upload the changes to the mainframe directly from the Visual Studio Code user interface. For more information, see [VSCode Extension for Zowe](#).

New in API Mediation Layer

API Mediation Layer Version 0.9.1 contains the following new functionality and features:

- You can now view the status of API Mediation Layer from the Zowe Desktop App (zLUX plug-in).
- API Mediation Layer now lets you define single instance services and route it through a gateway without having to apply code changes to the service.
- API Catalog contains the following new functionality and features:
 - The [Mineral](#) user interface framework was used to design the API Catalog user interface.
 - The [Swagger](#) user interface component was implemented for more standardized look and feel.
 - The Tile view now contains a Search bar.
- API Mediation Layer documentation now contains the following tutorials:
 - [Onboard an existing Java REST API service without Spring Boot with Zowe API Mediation Layer](#).
 - [Onboard an existing Spring Boot REST API service with Zowe API Mediation Layer](#).

Enhanced JES Explorer

A full-screen job output view is now available. You can view a single job output file in a full-screen text area, which removes the need to navigate via the job tree. Note that this view is currently only available via direct access to the explorer. It is not accessible via the Zowe Desktop app in this release. To open a file in full screen, you can use the following URL/parameters: <https://host:explorerSecurePort/explorer-jes/#/viewer?jobName=SAMPLEJOB&jobId=JOB12345&fileId=102>

What's changed

Naming

MVD is renamed to Zowe Desktop.

JES Explorer

Fixed an issue where text would fall out of line in the content viewer caused by special characters. This fix includes migration to the orion-editor-component as the content viewer.

MVS Explorer

Fixed an issue where deletion of a dataset member fails.

Zowe CLI

Important! Zowe CLI in Version 0.9.1 contains **breaking** changes. A **breaking** change can cause problems with existing functionality when you upgrade to Zowe CLI Version 0.9.1. For example, scripts that you wrote previously might fail, user profiles might become invalid, and the product might not integrate with plug-ins properly.

You will be impacted by the following changes if you update your version of Zowe to Version 0.9.1:

- The home directory for Zowe CLI, which contains the Zowe CLI logs, profiles, and plug-ins, was changed from `~/ .brightside` to `~/ .zowe`. The character `"~"` denotes your home directory on your computer, which is typically `C:/Users/<yourUserId>` on Windows operating systems. When you update to Zowe CLI Version 0.9.1 and issue `zowe` commands, the profiles that you created previously will not be available.

To correct this behavior and migrate from an older version Zowe CLI, complete the following steps:

1. Issue any `bright` command to create the `~/ .zowe` home directory.
 2. After you create the directory, copy the complete contents of the `~/ .brightside` directory to the newly created `~/ .zowe` directory. Copying the contents of the `~/ .brightside` directory to the `~/ .zowe` directory restores the profiles you created previously.
 3. To help ensure that your plug-ins function properly, reinstall the plug-ins that you installed with older versions of Zowe CLI.
- The environment variables that control logging and the location of your home directory were previously prefixed with `BRIGHTSIDE_`. They are now prefixed with `ZOWE_`. If you were not using the environment variables before this change, no action is required. If you were using the environment variables, update any usage of the variables.

The following environment variables are affected:

- `BRIGHTSIDE_CLI_HOME` changed to `ZOWE_CLI_HOME`
- `BRIGHTSIDE_IMPERATIVE_LOG_LEVEL` changed to `ZOWE_IMPERATIVE_LOG_LEVEL`
- `BRIGHTSIDE_APP_LOG_LEVEL` changed to `ZOWE_APP_LOG_LEVEL`

Version 0.9.0 (August 2018)

Version 0.9.0 is the first Open Beta version for Zowe. This version contains the following changes since the last Closed Beta version.

What's new

New component - API Mediation Layer

Zowe now contains a component named API Mediation Layer. You install API Mediation Layer when you install the Zowe runtime on z/OS. For more information, see [API Mediation Layer](#) and [Installing the Zowe Application Framework, explorer server, and API Mediation Layer](#).

What's changed

Naming

- The project is now named Zowe.
- Zoe Brightside is renamed to Zowe CLI.

Installation

- The System Display and Search Facility (SDSF) of z/OS is no longer a prerequisite for installing explorer server.
- The name of the PROC is now ZOWESVR rather than ZOESVR.

zLUX

The mainframe account under which the ZSS server runs must have UPDATE permission on the BPX.DAEMON and BPX.SERVER facility class profiles.

Explorer server

The URL to access the explorer server UI is changed from `https://<your.server>:<atlasport>/ui/#/` to the following ones:

- `https://<your.server>:<atlasport>/explorer-jes/#/`
- `https://<your.server>:<atlasport>/explorer-mvs/#/`
- `https://<your.server>:<atlasport>/explorer-uss/#/`

What's removed

Removed all references to SYSLOG.

Known issues

Security message when you open the Zowe Desktop

When you initially open the Zowe Desktop, a security message alerts you that you are attempting to open a site that has an invalid HTTPS certificate. Other applications within the Zowe Desktop might also encounter this message. To prevent this message, add the URLs that you see to your list of trusted sites.

Note: If you clear the browser cache, you must add the URL to your trusted sites again.

Message ICH408I during runtime

During runtime, the information message ICH408I may present identifying insufficient write authority to a number of resources, these resources may include:

- `zowe/explorer-server/wlp/usr/servers/.pid/Atlas.pid`
- `zowe/zlux-example-server/deploy/site/plugins/`
- `zowe/zlux-example-server/deploy/instance/plugins/`

Note: This should not affect the runtime operations of Zowe. This is a known issue and will be addressed in the next build.

Zowe Application Framework APIs

Zowe Application Framework APIs exist but are under development. Features might be reorganized if it simplifies and clarifies the API, and features might be added if applications can benefit from them.

Chapter 1. Zowe overview

Zowe offers modern interfaces to interact with z/OS and allows you to work with z/OS in a way that is similar to what you experience on cloud platforms today. You can use these interfaces as delivered or through plug-ins and extensions that are created by clients or third-party vendors.

Zowe consists of the following main components.

- **Zowe Application Framework:** Contains a Web user interface (UI) that provides a full screen interactive experience. The Web UI includes many interactions that exist in 3270 terminals and web interfaces such as IBM z/OSMF.
- **Explorer server:** Provides a range of APIs for the management of jobs, data sets and z/OS UNIX System Services files.
- **API Mediation Layer:** Provides an API abstraction layer through which APIs can be discovered, catalogued, and presented uniformly.
- **Zowe CLI:** Provides a command-line interface that lets you interact with the mainframe remotely and use common tools such as Integrated Development Environments (IDEs), shell commands, bash scripts, and build tools for mainframe development. It provides a set of utilities and services for application developers that want to become efficient in supporting and building z/OS applications quickly. Some Zowe extensions are powered by Zowe CLI, for example the [Visual Studio Code Extension for Zowe](#).

For details of each component, see the corresponding section.

Zowe Application Framework

The Zowe Application Framework modernizes and simplifies working on the mainframe. With the Zowe Application Framework, you can create applications to suit your specific needs. The Zowe Application Framework contains a web UI that has the following features:

- The web UI works with the underlying REST APIs for data, jobs, and subsystem, but presents the information in a full screen mode as compared to the command line interface.
- The web UI makes use of leading-edge web presentation technology and is also extensible through web UI plug-ins to capture and present a wide variety of information.
- The web UI facilitates common z/OS developer or system programmer tasks by providing an editor for common text-based files like REXX or JCL along with general purpose data set actions for both Unix System Services (USS) and Partitioned Data Sets (PDS) plus Job Entry System (JES) logs.

The Zowe Application Framework consists of the following components:

- **Zowe Desktop**

The desktop, accessed through a browser.

- **Zowe Application Server**

The Zowe Application Server runs the Zowe Application Framework. It consists of the Node.js server plus the Express.js as a webservices framework, and the proxy applications that communicate with the z/OS services and components.

- **ZSS Server**

The ZSS Server provides secure REST services to support the Zowe Application Server.

- **Application plug-ins**

Several application-type plug-ins are provided. For more information, see [Using the Zowe Application Framework application plug-ins](#).

Explorer server

The explorer server is a z/OS® RESTful web service and deployment architecture for z/OS microservices. The server is implemented as a Liberty Profile web application that uses z/OSMF services to provide a range of APIs for the management of jobs, data sets and z/OS UNIX™ System Services (USS) files.

These APIs have the following features:

- These APIs are described by the Open API Specification allowing them to be incorporated to any standard-based REST API developer tool or API management process.
- These APIs can be exploited by off-platform applications with proper security controls.

Any client application that calls RESTful APIs directly can use the explorer server.

As a deployment architecture, the explorer server accommodates the installation of other z/Tool microservices into its Liberty instance. These microservices can be used by explorer server APIs and client applications.

Zowe CLI

Zowe CLI is a command-line interface that lets application developers interact with the mainframe in a familiar format. Zowe CLI helps to increase overall productivity, reduce the learning curve for developing mainframe applications, and exploit the ease-of-use of off-platform tools. Zowe CLI lets application developers use common tools such as Integrated Development Environments (IDEs), shell commands, bash scripts, and build tools for mainframe development. It provides a set of utilities and services for application developers that want to become efficient in supporting and building z/OS applications quickly.

Zowe CLI provides the following benefits:

- Enables and encourages developers with limited z/OS expertise to build, modify, and debug z/OS applications.
- Fosters the development of new and innovative tools from a PC that can interact with z/OS.
- Ensure that business critical applications running on z/OS can be maintained and supported by existing and generally available software development resources.
- Provides a more streamlined way to build software that integrates with z/OS.

Note: For information about prerequisites, software requirements, installing and upgrading Zowe CLI, see [Installing Zowe](#).

Zowe CLI capabilities

With Zowe CLI, you can interact with z/OS remotely in the following ways:

- **Interact with mainframe files:** Create, edit, download, and upload mainframe files (data sets) directly from Zowe CLI.
- **Submit jobs:** Submit JCL from data sets or local storage, monitor the status, and view and download the output automatically.
- **Issue TSO and z/OS console commands:** Issue TSO and console commands to the mainframe directly from Zowe CLI.
- **Integrate z/OS actions into scripts:** Build local scripts that accomplish both mainframe and local tasks.
- **Produce responses as JSON documents:** Return data in JSON format on request for consumption in other programming languages.

For detailed information about the available functionality in Zowe CLI, see [Zowe CLI Command Groups](#).

For information about extending the functionality of Zowe CLI by installing plug-ins, see [Extending Zowe CLI](#).

Zowe CLI Third-Party software agreements

Zowe CLI uses the following third-party software:

Third-party Software	Version	File name
chalk	2.3.0	Legal_Doc_00002285_56.pdf
cli-table2	0.2.0	Legal_Doc_00002310_5.pdf
dataobject-parser	1.2.1	Legal_Doc_00002310_36.pdf
find-up	2.1.0	Legal_Doc_00002310_33.pdf
glob	7.1.1	Legal_Doc_00001713_45.pdf
js-yaml	3.9.0	Legal_Doc_00002310_16.pdf
jsonfile	4.0.0	Legal_Doc_00002310_40.pdf
jsonschema	1.1.1	Legal_Doc_00002310_17.pdf
levenshtein	1.0.5	See UNLICENSE
log4js	2.5.3	Legal_Doc_00002310_37.pdf
merge-objects	1.0.5	Legal_Doc_00002310_34.pdf
moment	2.20.1	Legal_Doc_00002285_25.pdf
mustache	2.3.0	Legal_Doc_mustache.pdf
node.js	6.11.1	Legal_Doc_nodejs.pdf

stack-trace	0.0.10	Legal_Doc_00002310_10.pdf
string-width	2.1.1	Legal_Doc_00002310_39.pdf
wrap-ansi	3.0.1	Legal_Doc_00002310_12.pdf
yamljs	0.3.0	Legal_Doc_00002310_13.pdf
yargs	8.0.2	Legal_Doc_00002310_1.pdf

Note: All trademarks, trade names, service marks, and logos referenced herein belong to their respective companies.

To read each complete license, navigate to the GitHub repository and download the file named Zowe_CLI_TPSRs.zip. The .zip file contains the licenses for all of the third-party components that Zowe CLI uses.

More Information:

- [System requirements for Zowe CLI](#)
- [Installing Zowe CLI](#)

API Mediation Layer

The API Mediation Layer provides a single point of access for mainframe service REST APIs. The layer offers enterprise, cloud-like features such as high-availability, scalability, dynamic API discovery, consistent security, a single sign-on experience, and documentation. The API Mediation Layer facilitates secure communication across loosely coupled microservices through the API Gateway. The API Mediation Layer includes an API Catalog that provides an interface to view all discovered microservices, their associated APIs, and Swagger documentation in a user-friendly manner. The Discovery Service makes it possible to determine the location and status of microservice instances running inside the ecosystem.

More Information: - [Onboard an existing Spring Boot REST API service using Zowe API Mediation Layer - Using API Catalog](#)

Key features

- High availability of services in which application instances on a failing node are distributed among surviving nodes
- Microservice UIs available through the API Gateway and API Catalog by means of reverse proxying
- Support for standardization and normalization of microservice URLs and routing to provide API Mediation Layer users with a consistent way of accessing microservices.
- Minimal effort to register a microservice with the gateway (configuration over code)
- Runs on Windows, Linux, and z/OS (target platform)
- Written in Java utilizing Spring Boot (2.x), Angular 5, and the Netflix CloudStack
- Supports multiple client types for discovery (including Spring Boot, Java, and NodeJS)
- Contains enablers that allow for easy discovery and exposure of REST APIs and Swagger documentation for each microservice

API Mediation Layer architecture

The following diagram illustrates the single point of access with the API Gateway and the interactions between the API Gateway, API Catalog, and the Discovery Service:

Components

The API Layer consists of the following key components:

API Gateway

The microservices that are contained within the ecosystem are located behind a reverse proxy. Clients interact with the gateway layer (reverse proxy). This layer forwards API requests to the appropriate corresponding service through the microservice endpoint UI. The gateway is built using Netflix Zuul and Spring Boot technology.

Discovery Service

The Discovery service is the central point in the API Gateway infrastructure that accepts "announcements of REST services" and serves as a repository of active services. Back-end microservices register with this service either directly by using a Eureka client. Non-Spring Boot applications register with the Discover Service indirectly through a Sidecar. The Discovery Service is built on Eureka and Spring Boot technology.

API Catalog

The API Catalog is the catalog of published APIs and their associated documentation that are discoverable or can be available if provisioned from the service catalog. The API documentation is visualized using the Swagger UI. The API Catalog contains APIs of services available as product versions. A service can be implemented by one or more service instances, which provide exactly the same service for high-availability or scalability.

More Information: - [Onboard an existing Spring Boot REST API service using Zowe API Mediation Layer - Using API Catalog](#)

Zowe API Mediation Layer Third-Party software agreements

Zowe API Mediation Layer uses the following third-party software:

Third-party Software	Version	File name

Note: All trademarks, trade names, service marks, and logos referenced herein belong to their respective companies.

To read each complete license, navigate to the GitHub repository and download the file named Zowe_APIML_TPSRs.zip. The .zip file contains the licenses for all of the third-party components that Zowe API Mediation Layer uses.

Chapter 2. Installing Zowe

Zowe consists of four main components: the Zowe Application Framework (zLUX), the explorer server, API Mediation Layer, and Zowe CLI. You install the Zowe Application Framework, the explorer server, and API Mediation on z/OS and install Zowe CLI on PC. The installations on z/OS and on PC are independent.

To get started with installing Zowe, review the [Installation roadmap](#) topic.

Installation roadmap

Installing Zowe involves several steps that you must complete in the appropriate sequence. Review the following installation roadmap that presents the task-flow for preparing your environment and installing and configuring Zowe before you begin the installation process.

Tasks	Description
1. Prepare your environment to meet the installation requirements.	See System requirements .
2. Obtain the Zowe installation files.	The Zowe installation files are released in a PAX file format. The PAX file contains the runtimes and the scripts to install and launch the z/OS runtime, as well as the Zowe CLI package. For information about how to download, prepare, and install the Zowe runtime, see Obtaining the installation files .
3. Allocate enough space for the installation.	The installation process requires approximately 1 GB of available space. Once installed on z/OS, API Mediation Layer requires approximately 150MB of space, the Zowe Application Framework requires approximately 50 MB of space before configuration, and explorer server requires approximately 200 MB. Zowe CLI requires approximately 200 MB of space on your PC.
4. Install components of Zowe.	To install Zowe runtime (Zowe Application Framework, explorer server, and API Mediation Layer) on z/OS, see Installing the Zowe runtime on z/OS . To install Zowe CLI on PC, see Installing Zowe CLI .

Tasks	Description
5. Verify that Zowe is installed correctly.	To verify that the Zowe Application Framework, explorer server, and API Mediation Layer are installed correctly, see Verifying installation . To verify that Zowe CLI is installed correctly, see Testing connection to z/OSMF .
6. Optional: Troubleshoot problems that occurred during installation.	See Troubleshooting the installation .

To uninstall Zowe, see [Uninstalling Zowe](#).

Obtaining installation files

The Zowe installation files are distributed as a PAX file that contains the runtimes and the scripts to install and launch the z/OS runtime and the runtime for the command line interface. For each release, there is a PAX file named `zowe-v.r.m.pax`, where

- `v` indicates the version
- `r` indicates the release number
- `m` indicates the modification number

The numbers are incremented each time a release is created so the higher the numbers, the later the release. Use your web browser to download the PAX file by saving it to a folder on your desktop.

You can download the PAX file from the [Zowe website](#). After you obtain the PAX file, verify the PAX file and prepare it to install the Zowe runtime.

Follow these steps:

1. Verify the downloaded PAX file.

After you download the PAX file, verify the integrity of the PAX file to ensure that the file you download is officially distributed by the Zowe project.

Notes:

- The commands in the following steps are tested on both Mac OS X V10.13.6 and Ubuntu V16.04 and V17.10.
- Ensure that you have GPG installed. Click [here](#) to download and install GPG.
- The `v.r.m` in the commands of this step is a variable. You must replace it with the actual PAX file version, for example, `0.9.0`.

- a. Verify the hash code.

Download the hash code file `zowe-v.r.m.pax.sha512` from the [Zowe website](#). Then, run the following commands to check:

```
(gpg --print-md SHA512 zowe-v.r.m.pax > zowe-v.r.m.pax.sha512.my) && diff
zowe-v.r.m.pax.sha512.my zowe-v.r.m.pax.sha512 && echo matched || echo "not
match"
```

When you see "matched", it means the PAX file that you download is the same one that is officially distributed by the Zowe project. You can delete the temporary "zowe-v.r.m.pax.sha512.my" file.

You can also use other commands such as `sha512`, `sha512sum`, or `openssl dgst -sha512` to generate SHA512 hash code. These hash code results are in a different format from what Zowe provides but the values are the same.

- b. Verify with signature file.

In addition to the SHA512 hash, the hash is also verifiable. This is done by digitally signing the hash text file with a KEY from one of the Zowe developers.

Follow these steps:

- a. Download the signature file `zowe-v.1.m.pax.asc` from [Zowe website](https://www.zowe.org/), and download the public key KEYS from <https://github.com/zowe/release-management/>.
- b. Import the public key with command `gpg --import KEYS`.
- c. If you have never used gpg before, generate keys with command `gpg --gen-key`.
- d. Sign the downloaded public key with command `gpg --sign-key DC8633F77D1253C3`.
- e. Verify the file with command `gpg --verify zowe-v.1.m.pax.asc zowe-v.1.m.pax`.
- f. Optional: You can remove the imported key with command: `gpg --delete-key DC8633F77D1253C3`.

When you see output similar to the followin one, it means the PAX file that you download is the same one that is officially distributed by the Zowe project.

```
gpg: Signature made Tue 14 Aug 2018 08:29:46 AM EDT gpg: using RSA key
DC8633F77D1253C3 gpg: Good signature from "Matt Hogstrom (CODE SIGNING KEY)"
" [full]
```

2. Transfer the PAX file to z/OS.

- a. Open a terminal in Mac OS/Linux, or command prompt in Windows OS, and navigate to the directory where you downloaded the Zowe PAX file.

- b. Connect to z/OS using SFTP. Issue the following command:

```
sftp <userID@ip.of.zos.box>
```

If SFTP is not available or if you prefer to use FTP, you can issue the following command instead:

```
ftp <userID@ip.of.zos.box>
```

Note: When you use FTP, switch to binary file transfer mode by issuing the following command:

```
bin
```

- c. Navigate to the target directory that you wish to transfer the Zowe PAX file into on z/OS.

Note: After you connect to z/OS and enter your password, you enter into the Unix file system. The following commands are useful:

- To see what directory you are in, type `pwd`.
- To switch directory, type `cd`.
- To list the contents of a directory, type `ls`.
- To create a directory, type `mkdir`.

- d. When you are in the directory you want to transfer the Zowe PAX file into, issue the following command:

```
put <pax-file-name>.pax
```

Where *pax-file-name* is a variable that indicates the full name of the PAX file you downloaded.

Note: When your terminal is connected to z/OS through FTP or SFTP, you can prepend commands with `!` to have them issued against your desktop. To list the contents of a directory on your desktop, type `lls` where `ls` will list contents of a directory on z/OS.

3. When the PAX file is transferred, expand the PAX file by issuing the following command in an ssh session:

```
pax -ppx -rf <pax-file-name>.pax
```

Where *pax-file-name* is a variable that indicates the name of the PAX file you downloaded.

This will expand to a file structure.

```
/files
/install
/scripts
...
```

Note: The PAX file will expand into the current directory. A good practice is to keep the installation directory apart from the directory that contains the PAX file. To do this, you can create a directory such as `/zowe/paxes` that contains the PAX files, and another such as `/zowe/builds`. Use SFTP to transfer the Zowe PAX file into the `/zowe/paxes` directory, use the `cd` command to switch into `/zowe/builds` and issue the command `pax -ppx -rf ../paxes/<zowe-v.r.m>.pax`. The `/install` folder will be created inside the `zowe/builds` directory from where the installation can be launched.

Installing the Zowe Application Framework, explorer server, and API Mediation Layer

You install the Zowe Application Framework, explorer server, and API Mediation Layer on z/OS.

Before you install the runtime on z/OS, ensure that your environment meets the requirements. See [System requirements](#).

Installing the Zowe runtime on z/OS

To install API Mediation Layer, the Zowe Application Framework, and explorer server, you install the Zowe runtime on z/OS.

Follow these steps:

1. Navigate to the directory where the installation archive is extracted. Locate the `/install` directory.

```
/install
/zowe-install.sh
/zowe-install.yaml
```

2. Review the `zowe-install.yaml` file which contains the following properties:

- `install:rootDir` is the directory that Zowe will be installed into to create a Zowe runtime. The default directory is `~/zowe/0.9.2`. The user's home directory is the default value to ensure that the installing user has permission to create the directories that are required for the install. If the Zowe runtime will be maintained by multiple users it might be more appropriate to use another directory, such as `/var/zowe/v.r.m`.

You can run the installation process multiple times with different values in the `zowe-install.yaml` file to create separate installations of the Zowe runtime. The directory that Zowe is installed into must be empty. The install script exits if the directory is not empty and creates the directory if it does not exist.

- API Mediation Layer has three ports - two HTTP ports and one HTTPS port, each for a micro-service.
- Explorer-server has two ports - one for HTTP and one for HTTPS. The liberty server is used for the explorer-ui components.
- zlux-server has three ports - the HTTP and HTTPS ports that are used by the Zowe Application Server, and the port that is used by the ZSS Server.

```
install:
  rootDir=/var/zowe/0.9.2

api-mediation:
  catalogHttpPort=7552
  discoveryHttpPort=7553
  gatewayHttpsPort=7554
```

```
explorer-server:
  httpPort=7080
  httpsPort=7443

# http and https ports for the node server
zlux-server:
  httpPort=8543
  httpsPort=8544
  zssPort=8542
```

If all of the default port values are acceptable, then you do not need to change them. The ports must not be in use for the Zowe runtime servers to be able to allocate them.

To determine which ports are not available, follow these steps:

- To display a list of ports that are in use, issue the following command:

```
TSO NETSTAT
```

- To display a list of reserved ports, issue the following command:

```
TSO NETSTAT PORTLIST
```

The `zowe-install.yaml` also contains the telnet and SSH port with defaults of 23 and 22. If your z/OS LPAR is using different ports, edit the values. This is to allow the TN3270 terminal desktop application to connect as well as the VT terminal desktop application. Unlike the ports needed by the Zowe runtime for its Zowe Application Framework and explorer server which must be unused, the terminal ports are expected to be in use.

```
# Ports for the TN3270 and the VT terminal to connect to
terminals:
  sshPort=22
  telnetPort=23
```

3. Execute the `zowe-install.sh` script.

With the current directory being the `/install` directory, execute the script `zowe-install.sh` by issuing the following command:

```
zowe-install.sh
```

You might receive the following error that the file cannot be executed.

```
zowe-install.sh: cannot execute
```

The error is due to that the install script does not have execute permission. To add execute permission, issue the following command:

```
chmod u+x zowe-install.sh.
```

4. Configure Zowe as a started task.

The ZOWESVR must be configured as a started task (STC) under the IZUSVR user ID.

- If you use RACF, issue the following commands:

```
RDEFINE STARTED ZOWESVR.* UACC(NONE) STDATA(USER(IZUSVR) GROUP(IZUADMIN) PRIVILEGED(NO)
  TRUSTED(NO) TRACE(YES))
SETROPTS REFRESH RACLIST(STARTED)
```

- If you use CA ACF2, issue the following commands:

```
SET CONTROL(GSO)
INSERT STC.ZOWESVR LOGONID(IZUSVR) GROUP(IZUADMIN) STCID(ZOWESVR)
F ACF2,REFRESH(STC)
```

- If you use CA Top Secret, issue the following commands:

```
TSS ADDTO(STC) PROCNAME(ZOWESVR) ACID(IZUSVR)
```

5. Add the users to the required groups, IZUADMIN for administrators and IZUUSER for standard users.

- If you use RACF, issue the following command:

```
CONNECT (userid) GROUP(IZUADMIN)
```

- If you use CA ACF2, issue the following commands:

```
ACFNRULE TYPE(TGR) KEY(IZUADMIN) ADD(UID(<uid string of user>) ALLOW)
F ACF2,REBUILD(TGR)
```

- If you use CA Top Secret, issue the following commands:

```
TSS ADD(userid) PROFILE(IZUADMIN)
TSS ADD(userid) GROUP(IZUADMGP)
```

When the `zowe-install.sh` script runs, it performs a number of steps broken down into sections. These are covered more in the section [Troubleshooting the installation](#).

Starting and stopping the Zowe runtime on z/OS

Zowe has three runtime components on z/OS, the explorer server, the Zowe Application Server, and API Mediation Layer. When you run the ZOWESVR PROC, it starts all these components. The Zowe Application Server startup script also starts the zSS server, so starting the ZOWESVR PROC starts all the four servers, and stopping it stops all four.

Starting the ZOWESVR PROC

To start the ZOWESVR PROC, run the `zowe-start.sh` script at the Unix Systems Services command prompt:

```
cd $ZOWE_ROOT_DIR/scripts
./zowe-start.sh
```

where `$ZOWE_ROOT_DIR` is the directory where you installed the Zowe runtime. This script starts the ZOWESVR PROC for you so you don't have to log on to TSO and use SDSF.

Note: The default startup allows self signed and expired certificates from the Zowe Application Framework proxy data services such as the explorer server.

If you prefer to use SDSF to start Zowe, start ZOWESVR by issuing the following operator command in SDSF:

```
/S ZOWESVR
```

By default, Zowe uses the runtime version that you most recently installed. To start a different runtime, specify its server path on the START command:

```
/S ZOWESVR,SRVRPATH='$ZOWE_ROOT_DIR/explorer-server'
```

To test whether the explorer server is active, open the URL `https://<hostname>:7443/explorer-mvs`.

The port number 7443 is the default port and can be overridden through the `zowe-install.yaml` file before the `zowe-install.sh` script is run. See [Installing Zowe runtime on z/OS](#).

Stopping the ZOWESVR PROC

To stop the ZOWESVR PROC, run the `zowe-stop.sh` script at the Unix Systems Services command prompt:

```
cd $ZOWE_ROOT_DIR/scripts
./zowe-stop.sh
```

If you prefer to use SDSF to stop Zowe, stop ZOWESVR by issuing the following operator command in SDSF:

```
/C ZOWESVR
```

Either of the methods will stop the explorer server, the Zowe Application Server, and the zSS server.

When you stop the ZOWESVR, you might get the following error message:

```
IEE842I ZOWESVR DUPLICATE NAME FOUND- REENTER COMMAND WITH 'A='
```

This is because there is more than one started task named ZOWESVR. To resolve the issue, stop the required ZOWESVR instance by issuing the following commands:

```
/C ZOWESVR,A=asid
```

You can obtain the *asid* from the value of `A=asid` when you issue the following commands:

```
/D A,ZOWESVR
```

Verifying installation

After you complete the installation of API Mediation, Zowe Application Framework, and explorer server, use the following procedures to verify that the components are installed correctly and are functional.

Verifying Zowe Application Framework installation

If the Zowe Application Framework is installed correctly, you can open the Zowe Desktop from a supported browser.

From a supported browser, open the Zowe Desktop at `https://myhost:httpsPort/ZLUX/plugins/com.rs.mvd/web/index.html`

where:

- *myHost* is the host on which you installed the Zowe Application Server.
- *httpPort* is the port number that is assigned to `node.http.port` in `zluxserver.json`.
- *httpsPort* is the port number that is assigned to `node.https.port` in `zluxserver.json`. For example, if the Zowe Application Server runs on host *myhost* and the port number that is assigned to `node.http.port` is 12345, you specify `https://myhost:12345/ZLUX/plugins/com.rs.mvd/web/index.htm`.

Verifying explorer server installation

After explorer server is installed and the ZOWESVR procedure is started, you can verify the installation from an Internet browser by using the following case-sensitive URL:

```
https://<your.server>:<atlasport>/api/v1/system/version
```

where *your.server* is the host name or IP address of the z/OS® system where explorer server is installed, and *atlasport* is the port number that is chosen during installation. You can verify the port number in the `server.xml` file that is located in the explorer server installation directory, which is `/var/zowe/explorer-server/wlp/usr/servers/Atlas/server.xml` by default. Look for the `httpsPort` assignment in the `server.xml` file, for example: `httpPort="7443"`.

This URL sends an HTTP GET request to the Liberty Profile explorer server. If explorer server is installed correctly, a JSON payload that indicates the current explorer server application version is returned. For example:

```
{ "version": "V0.0.1" }
```

Note: The first time that you interact with the explorer server, you are prompted to enter an MVS™ user ID and password. The MVS user ID and password are passed over the secure HTTPS connection to establish authentication.

After you verify that explorer server is successfully installed, you can access the UI at the following URLs:

- <https://<your.server>:<atlasport>/ui/v1/jobs/#/>
- <https://<your.server>:<atlasport>/ui/v1/datasets/#/>
- <https://<your.server>:<atlasport>/ui/v1/uss/#/>

If explorer server is not installed successfully, see [Troubleshooting installation](#) for solutions.

Verifying the availability of explorer server REST APIs

To verify the availability of all explorer server REST APIs, use the Liberty Profile's REST API discovery feature from an internet browser with the following URL. This URL is case-sensitive.

https://<your.server>:<atlasport>/ibm/api/explorer

With the discovery feature, you can also try each discovered API. The users who verify the availability must have access to their data sets and job information by using relevant explorer server APIs. This ensures that your z/OSMF configuration is valid, complete, and compatible with the explorer server application. For example, try the following APIs:

Explorer server: JES Jobs APIs

```
GET /api/v1/jobs
```

This API returns job information for the calling user.

Explorer server: Data set APIs

```
GET /api/v1/datasets/userid.**
```

This API returns a list of the userid.** MVS data sets.

Verifying API Mediation installation

Use your preferred REST API client to review the value of the status variable of the API Catalog service that is routed through the API Gateway using the following URL:

https://hostName:basePort/api/v1/apicatalog/application/state

The `hostName` is set during install, and `basePort` is set as the `gatewayHttpsPort` parameter.

Example:

The following example illustrates how to use the **curl** utility to invoke API Mediation Layer endpoint and the **grep** utility to parse out the response status variable value

```
$ curl -v -k --silent https://hostName:basePort/api/v1/apicatalog/application/state 2>&1 | grep -Po '(?<="status"\:")[^"]+'
|IP
```

The response UP confirms that API Mediation Layer is installed and is running properly.

Installing Zowe CLI

As a systems programmer or application developer, you install Zowe CLI on your PC.

Methods to install Zowe CLI

You can use either of the following methods to install Zowe CLI.

- [Install Zowe CLI from local package](#)
- [Install Zowe CLI from online registry](#)

If you encounter problems when you attempt to install Zowe CLI, see [Troubleshooting installing Zowe CLI](#).

Installing Zowe CLI from local package

If you do not have internet access at your site, use the following method to install Zowe CLI from a local package.

Follow these steps:

1. Ensure that the following prerequisite software is installed on your PC:

- **[Node.js V8.0 or later](#)**

Tip: You might need to restart the command prompt after installing Node.js. Issue the command `node --version` to verify that Node.js is installed.

- **[Node Package Manager V5.0 or later](#)**

npm is included with the Node.js installation. Issue the command `npm --version` to verify that npm is installed.

2. Obtain the Zowe installation files, which includes the `zowe-cli-bundle.zip` file. Use FTP to distribute the zip file to client workstations.
3. Open a command line window. For example, Windows Command Prompt. Browse to the directory where you downloaded the Zowe CLI installation bundle (.zip file). Issue the following command to unzip the files:

```
unzip zowe-cli-bundle.zip
```

The command expands files into your working directory for Zowe CLI and Zowe CLI plug-ins.

4. Issue the following command to install Zowe CLI on your PC:

```
npm install -g zowe-cli-<VERSION_NUMBER>.tgz
```

- **[<VERSION_NUMBER>](#)**

The version of Zowe CLI that you want to install from the package. The following is an example of a full package name for Zowe CLI: `zowe-core-2.0.0-next.201810161407.tgz`

Important! On Windows, you must run as an Administrator to install the product and plug-ins.

Note: On Linux, you might need to prepend `sudo` to your npm commands so that you can issue the install and uninstall commands. For more information, see [Troubleshooting installing Zowe CLI](#).

Zowe CLI is installed on your PC. See [Installing Plug-ins](#) for information about the commands for installing plug-ins from the package.

5. Create a `zosmf` profile so that you can issue commands that communicate with z/OSMF.

Note: For information about how to create a profile, see [Creating a Zowe CLI profile](#).

Tip: Zowe CLI profiles contain information that is required for the product to interact with remote systems. For example, host name, port, and user ID. Profiles let you target unique systems, regions, or instances for a command. Most Zowe CLI [command groups](#) require a Zowe CLI `zosmf` profile.

After you install and configure Zowe CLI, you can issue the `zowe --help` command to view a list of available commands. For more information, see [Display Help](#).

Installing Zowe CLI from online registry

If your PC is connected to the Internet, you can use the following method to install Zowe CLI from an npm registry.

Follow these steps:

1. Ensure that the following prerequisite software is installed on your PC:

- **Node.js V8.0 or later**

Tip: You might need to restart the command prompt after installing Node.js. Issue the command `node --version` to verify that Node.js is installed.

- **Node Package Manager V5.0 or later**

npm is included with the Node.js installation. Issue the command `npm --version` to verify that npm is installed.

2. Issue the following command to set the registry to the Zowe CLI scoped package on Bintray. In addition to setting the scoped registry, your non-scoped registry must be set to an npm registry that includes all of the dependencies for Zowe CLI, such as the global npm registry:

```
npm config set @brightside:registry https://api.bintray.com/npm/ca/brightside
```

3. Issue the following command to install Zowe CLI from the registry:

```
npm install -g @brightside/core@next
```

Important! On Windows, you must run as an Administrator to install the product and plug-ins.

4. (Optional) To install all available plug-ins to Zowe CLI, issue the following command:

```
bright plugins install @brightside/cics@next
```

Note: For more information about how to install multiple plug-ins, update to a specific version of a plug-in, and install from specific registries, see [Installing plug-ins](#).

5. Create a zosmf profile so that you can issue commands that communicate with z/OSMF. For information about how to create a profile, see [Creating a Zowe CLI profile](#).

Tip: Zowe CLI profiles contain information that is required for the product to interact with remote systems. For example, host name, port, and user ID. Profiles let you target unique systems, regions, or instances for a command. Most Zowe CLI [command groups](#) require a Zowe CLI zosmf profile.

After you install and configure Zowe CLI, you can issue the `zowe --help` command to view a list of available commands. For more information, see [How to display Zowe CLI help](#).

Creating a Zowe CLI profile

Profiles are a Zowe CLI functionality that let you store configuration information for use on multiple commands. You can create a profile that contains your username, password, and connection details for a particular mainframe system, then reuse that profile to avoid typing it again on every command. You can switch between profiles to quickly target different mainframe subsystems.

Important! A zosmf profile is required to issue most Zowe CLI commands. The first profile that you create becomes your default profile. When you issue any command that requires a zosmf profile, the command executes using your default profile unless you specify a specific profile name on that command.

Follow these steps:

1. To create a zosmf profile, issue the following command. Refer to the available options in the help text to define your profile:

```
zowe profiles create zosmf-profile --help
```

Note: After you create a profile, verify that it can communicate with z/OSMF. For more information, see (#Testing Zowe CLI connection to z/OSMF).

Testing Zowe CLI connection to z/OSMF

After you configure a Zowe CLI `zosmf` profile to connect to z/OSMF on your mainframe systems, you can issue a command at any time to receive diagnostic information from the server and confirm that your profile can communicate with z/OSMF.

Tip: In this documentation we provide command syntax to help you create a basic profile. We recommend that you append `--help` to the end of commands in the product to see the complete set of commands and options available to you. For example, issue `zowe profiles --help` to learn more about how to list profiles, switch your default profile, or create different profile types.

After you create a profile, run a test to verify that Zowe CLI can communicate properly with z/OSMF. You can test your default profile and any other Zowe CLI profile that you created.

Default profile

- Verify that you can use your default profile to communicate with z/OSMF by issuing the following command:

```
zowe zosmf check status
```

Specific profile

- Verify that you can use a specific profile to communicate with z/OSMF by issuing the following command:

```
zowe zosmf check status --zosmf-profile <profile_name>
```

The commands return a success or failure message and display information about your z/OSMF server. For example, the z/OSMF version number and a list of installed plug-ins. Report any failure to your systems administrator and use the information for diagnostic purposes.

Troubleshooting the installation

Review the following troubleshooting tips if you have problems with Zowe installation.

Troubleshooting installing the Zowe runtime

1. Environment variables

To prepare the environment for the Zowe runtime, a number of ZFS folders need to be located for prerequisites on the platform that Zowe needs to operate. These can be set as environment variables before the script is run. If the environment variables are not set, the install script will attempt to locate default values.

- `ZOWE_ZOSMF_PATH`: The path where z/OSMF is installed. Defaults to `/usr/lpp/zosmf/lib/defaults/servers/zosmfServer`
- `ZOWE_JAVA_HOME`: The path where 64 bit Java 8 or later is installed. Defaults to `/usr/lpp/java/J8.0_64`
- `ZOWE_EXPLORER_HOST`: The IP address of where the explorer servers are launched from. Defaults to running `hostname -c`

The first time the script is run if it has to locate any of the environment variables, the script will add lines to the current user's home directory `.profile` file to set the variables. This ensures that the next time the same user runs the install script, the previous values will be used.

Note: If you wish to set the environment variables for all users, add the lines to assign the variables and their values to the file `/etc/.profile`.

If the environment variables for ZOWE_ZOSMF_PATH, ZOWE_JAVA_HOME are not set and the install script cannot determine a default location, the install script will prompt for their location. The install script will not continue unless valid locations are provided.

2. Expanding the PAX files

The install script will create the Zowe runtime directory structure using the `install:rootDir` value in the `zowe-install.yaml` file. The runtime components of the Zowe server are then unpxed into the directory that contains a number of directories and files that make up the Zowe runtime.

If the expand of the PAX files is successful, the install script will report that it ran its install step to completion.

3. Changing Unix permissions

After the install script lay down the contents of the Zowe runtime into the `rootDir`, the next step is to set the file and directory permissions correctly to allow the Zowe runtime servers to start and operate successfully.

The install process will execute the file `scripts/zowe-runtime-authorize.sh` in the Zowe runtime directory. If the script is successful, the result is reported. If for any reason the script fails to run because of insufficient authority by the user running the install, the install process reports the errors. A user with sufficient authority should then run the `zowe-runtime-authorize.sh`. If you attempt to start the Zowe runtime servers without the `zowe-runtime-authorize.sh` having successfully completed, the results are unpredictable and Zowe runtime startup or runtime errors will occur.

4. Creating the PROCLIB member to run the Zowe runtime

Note: The name of the PROCLIB member might vary depending on the standards in place at each z/OS site, however for this documentation, the PROCLIB member is called ZOWESVR.

At the end of the installation, a Unix file `ZOWESVR.jcl` is created under the directory where the runtime is installed into, `$INSTALL_DIR/files/templates`. The contents of this file need to be tailored and placed in a JCL member of the PROCLIB concatenation for the Zowe runtime to be executed as a started task. The install script does this automatically, trying data sets `USER.PROCLIB`, other PROCLIB data sets found in the PROCLIB concatenation and finally `SYS1.PROCLIB`.

If this succeeds, you will see a message like the following one:

```
PROC ZOWESVR placed in USER.PROCLIB
```

Otherwise you will see messages beginning with the following information:

```
Failed to put ZOWESVR.JCL in a PROCLIB dataset.
```

In this case, you need to copy the PROC manually. Issue the TSO `oget` command to copy the `ZOWESVR.jcl` file to the preferred PROCLIB:

```
oget '$INSTALL_DIR/files/templates/ZOWESVR.jcl' 'MY.USER.PROCLIB(ZOWESVR)'
```

You can place the PROC in any PROCLIB data set in the PROCLIB concatenation, but some data sets such as `SYS1.PROCLIB` might be restricted, depending on the permission of the user.

You can tailor the JCL at this line

```
//ZOWESVR PROC SRVRPATH='/zowe/install/path/explorer-server'
```

to replace the `/zowe/install/path` with the location of the Zowe runtime directory that contains the explorer server. Otherwise you must specify that path on the `START` command when you start Zowe in SDSF:

```
/S ZOWESVR,SRVRPATH='$ZOWE_ROOT_DIR/explorer-server'
```

Troubleshooting installing the Zowe Application Framework

To help Zowe research any problems you might encounter, collect as much of the following information as possible and open an issue in GitHub with the collected information.

- Zowe version and release level
- z/OS release level
- Job output and dump (if any)
- Javascript console output (Web Developer toolkit accessible by pressing F12)
- Log output from the Zowe Application Server
- Error message codes
- Screenshots (if applicable)
- Other relevant information (such as the version of Node.js that is running on the Zowe Application Server and the browser and browser version).

Troubleshooting installing explorer server

If explorer server REST APIs do not function properly, check the following items:

- Check whether your Liberty explorer server is running.

You can check this in the Display Active (DA) panel of SDSF under ISPF. The ZOWESVR started task should be running. If the ZOWESVR task is not running, start the explorer server by using the following START operator command:

```
/S ZOWESVR
```

You can also use the operator command /D A,ZOWESVR to verify whether the task is active, which alleviates the need for the DA panel of SDSF. If the started task is not running, ensure that your ZOWESVR procedure resides in a valid PROCLIB data set, and check the task's job output for errors.

- Check whether the explorer server is started without errors.

In the DA panel of SDSF under ISPF, select the ZOWESVR job to view the started task output. If the explorer server is started without errors, you can see the following messages:

```
CWWKE0001I: The server Atlas has been launched.
```

```
CWWKF0011I: The server Atlas is ready to run a smarter planet.
```

If you see error messages that are prefixed with "ERROR" or stack traces in the ZOWESVR job output, respond to them.

- Check whether the URL that you use to call explorer server REST APIs is correct. For example: <https://your.server:atlasport/api/v1/system/version>. The URL is case-sensitive.
- Ensure that you enter a valid z/OS® user ID and password when initially connecting to the explorer server.
- If testing the explorer server REST API for jobs information fails, check the z/OSMF IZUSVR1 task output for errors. If no errors occur, you can see the following messages in the IZUSVR1 job output:

```
CWWKE0001I : The server zosmfServer has been launched.
```

```
CWWKF0011I: The server zosmfServer is ready to run a smarter planet.
```

If you see error messages, respond to them.

For RESTJOBS, you can see the following message if no errors occur:

```
CWWKZ0001I: Application IzuManagementFacilityRestJobs started in n.nnn seconds.
```

You can also call z/OSMF RESTJOBS APIs directly from your Internet browser with a URL, for example,

```
https://your.server:securezosmfport/zosmf/restjobs/jobs
```

where the *securezosmfport* is 443 by default. You can verify the port number by checking the *izu.https.port* variable assignment in the *z/OSMF bootstrap.properties* file.

You might get error message IZUG846W, which indicates that a cross-site request forgery (CSRF) was attempted. To resolve the issue, update your browser by adding the X-CSRF-ZOSMF-HEADER HTTP custom header to every cross-site request. This header can be set to any value or an empty string (""). For details, see the *z/OSMF* documentation. If calling the *z/OSMF* RESTJOBS API directly fails, fix *z/OSMF* before explorer server can use these APIs successfully.

- If testing the explorer server REST API for data set information fails, check the *z/OSMF* IZUSVR1 task output for errors and confirm that the *z/OSMF* RESTFILES services are started successfully. If no errors occur, you can see the following message in the IZUSVR1 job output:

```
CWWKZ0001I: Application IzuManagementFacilityRestFiles started in n.nnn seconds.
```

To test *z/OSMF* REST APIs you can run curl scripts from your workstation.

```
curl --user <username>:<password> -k -X GET --header 'Accept: application/json' --header 'X-CSRF-ZOSMF-HEADER: true' "https://<z/os host name>:<securezosmfport>/zosmf/restjobs/jobs?prefix=*&owner=*
```

where the *securezosmfport* is 443 by default. You can verify the port number by checking the *izu.https.port* variable assignment in the *z/OSMF bootstrap.properties* file.

/zosmf/restjobs/jobs?prefix=&owner=** will return a list of the jobs.

If *z/OSMF* returns jobs correctly you can test whether it is able to return files using

```
curl --user <username>:<password> -k -X GET --header 'Accept: application/json' --header 'X-CSRF-ZOSMF-HEADER: true' "https://<z/os host name>:<securezosmfport>/zosmf/restfiles/ds?dslevel=SYS1"
```

If the restfiles curl statement returns a TSO SERVLET EXCEPTION error check that the *z/OSMF* installation step of creating a valid IZUFPROC procedure in your system PROCLIB has been completed. For more information, see the [z/OSMF Configuration Guide](#).

The IZUFPROC member resides in your system PROCLIB, which is similar to the following sample:

```
//IZUFPROC PROC ROOT='/usr/lpp/zosmf' /* zOSMF INSTALL ROOT */
//IZUFPROC EXEC PGM=IKJEFT01,DYNAMNBR=200
//SYSEXEC DD DISP=SHR,DSN=ISP.SISPEXEC
// DD DISP=SHR,DSN=SYS1.SBPXEXEC
//SYSPROC DD DISP=SHR,DSN=ISP.SISPCLIB
// DD DISP=SHR,DSN=SYS1.SBPXEXEC
//ISPLLIB DD DISP=SHR,DSN=SYS1.SIEALNKE
//ISPPLIB DD DISP=SHR,DSN=ISP.SISPPENU
//ISPTLIB DD RECFM=FB,LRECL=80,SPACE=(TRK,(1,0,1))
// DD DISP=SHR,DSN=ISP.SISPTENU
//ISPSLIB DD DISP=SHR,DSN=ISP.SISPSENU
//ISPMLIB DD DISP=SHR,DSN=ISP.SISPMENU
//ISPPROF DD DISP=NEW,UNIT=SYSDA,SPACE=(TRK,(15,15,5)),
// DCB=(RECFM=FB,LRECL=80,BLKSIZE=3120)
//IZUSRVP DD PATH='&ROOT./defaults/izurf.tsoservlet.mapping.json'
//SYSOUT DD SYSOUT=H
//CEEDUMP DD SYSOUT=H
//SYSUDUMP DD SYSOUT=H
//
```

Note: You might need to change paths and data sets names to match your installation.

A known issue and workaround for RESTFILES API can be found at [TSO SERVLET EXCEPTION ATTEMPTING TO USE RESTFILE INTERFACE](#).

- Check your system console log for related error messages and respond to them.

If the explorer server cannot connect to the *z/OSMF* server, check the following item:

By default, the explorer server communicates with the *z/OSMF* server on the localhost address. If your *z/OSMF* server is on a different IP address to the explorer server, for example, if you are running *z/OSMF*

with Dynamic Virtual IP Addressing (DVIPA), you can change this by adding a ZOSMF_HOST parameter to the `server.env` file. For example: `ZOSMF_HOST=winmvs27`.

Troubleshooting installing Zowe CLI

The following topics contain information that can help you troubleshoot problems when you encounter unexpected behavior using Zowe CLI.

npm install -g Command Fails Due to an EPERM Error

Valid on Windows

Symptom:

This behavior is due to a problem with Node Package Manager (npm). There is an open issue on the npm GitHub repository to fix the defect.

Solution:

If you encounter this problem, some users report that repeatedly attempting to install Zowe CLI yields success. Some users also report success using the following workarounds:

- Issue the `npm cache clean` command.
- Uninstall and reinstall Zowe CLI. For more information, see [Install Zowe CLI](#).
- Add the `--no-optional` flag to the end of the `npm install` command.

Sudo syntax required to complete some installations

Valid on Linux

Symptom:

The installation fails on Linux.

Solution:

Depending on how you configured Node.js on Linux or Mac, you might need to add the prefix `sudo` before the `npm install -g` command or the `npm uninstall -g` command. This step gives Node.js write access to the installation directory.

npm install -g command fails due to npm ERR! Cannot read property 'pause' of undefined error

Valid on Windows or Linux

Symptom:

You receive the error message `npm ERR! Cannot read property 'pause' of undefined` when you attempt to install the product.

Solution:

This behavior is due to a problem with Node Package Manager (npm). If you encounter this problem, revert to a previous version of npm that does not contain this defect. To revert to a previous version of npm, issue the following command:

```
npm install npm@5.3.0 -g
```

Node.js commands do not respond as expected

Valid on Windows or Linux

Symptom:

You attempt to issue node.js commands and you do not receive the expected output.

Solution:

There might be a program that is named *node* on your path. The Node.js installer automatically adds a program that is named *node* to your path. When there are pre-existing programs that are named *node* on your computer, the program that appears first in the path is used. To correct this behavior, change the order of the programs in the path so that Node.js appears first.

Installation fails on Oracle Linux 6

Valid on Oracle Linux 6

Symptom:

You receive error messages when you attempt to install the product on an Oracle Linux 6 operating system.

Solution:

Install the product on Oracle Linux 7 or another Linux or Windows OS. Zowe CLI is not compatible with Oracle Linux 6.

Uninstalling Zowe

You can uninstall Zowe if you no longer need to use it. Follow these procedures to uninstall each Zowe component.

- [Uninstalling the Zowe Application Framework](#)
- [Uninstalling explorer server](#)
- [Uninstalling API Mediation Layer](#)
- [Uninstalling Zowe CLI](#)

Uninstalling the Zowe Application Framework

Follow these steps:

1. The Zowe Application Server (zlux-server) runs under the ZOWESVR started task, so it should terminate when ZOWESVR is stopped. If it does not, use one of the following standard process signals to stop the server:
 - SIGHUP
 - SIGTERM
 - SIGKILL
2. Delete or overwrite the original directories. If you modified the `zluxserver.json` file so that it points to directories other than the default directories, do not delete or overwrite those directories.

Uninstalling explorer server

Follow these steps:

1. Stop your Explorer Liberty server by running the following operator command:

```
C ZOWESVR
```

2. Delete the ZOWESVR member from your system PROCLIB data set.

To do this, you can issue the following TSO DELETE command from the TSO READY prompt or from ISPF option 6:

```
delete 'your.zowe.proclib(zowesvr)'
```

Alternatively, you can issue the TSO DELETE command at any ISPF command line by prefixing the command with TSO:

```
tso delete 'your.zowe.proclib(zowesvr)'
```

To query which PROCLIB data set that ZOWESVR is put in, you can view the SDSF JOB log of ZOWESVR and look for the following message:

```
IEFC001I PROCEDURE ZOWESVR WAS EXPANDED USING SYSTEM LIBRARY your.zowe.proclib
```

If no ZOWESVR JOB log is available, issue the /\$D PROCLIB command at the SDSF COMMAND INPUT line and BROWSE each of the DSNAMESOME.JES.PROCLIB output lines in turn with ISPF option 1, until you find the first data set that contains member ZOWESVR. Then issue the DELETE command as shown above.

3. Remove RACF® (or equivalent) definitions with the following command:

```
RDELETE STARTED (ZOWESVR.*)  
SETR RACLIST(STARTED) REFRESH  
REMOVE (userid) GROUP(IZUUSER)
```

where *userid* indicates the user ID that is used to install Zowe.

4. Delete the z/OS® UNIX™ System Services explorer server directory and files from the explorer server installation directory by issuing the following command:

```
rm -R /var/zowe /*Explorer Server Installation Directory*
```

Or

```
rm -R /var/zowe/<v.r.m> /*Explorer Server Installation Directory*
```

Where <v.r.m> indicates the package version such as 0.9.0.

Notes:

- You might need super user authority to run this command.
- You must identify the explorer server installation directory correctly. Running a recursive remove command with the wrong directory name might delete critical files.

Uninstalling API Mediation Layer

Note: Be aware of the following considerations:

- You might need super-user authority to run this command.
- You must identify the API Mediation installation directory correctly. Running a recursive remove command with the incorrect directory name can delete critical files.

Follow these steps:

1. Stop your API Mediation Layer services using the following command:

```
C ZOWESVR
```

2. Delete the ZOWESVR member from your system PROCLIB data set.

To do this, you can issue the following TSO DELETE command from the TSO READY prompt or from ISPF option 6:

```
delete 'your.zowe.proclib(zowesvr)'
```

Alternatively, you can issue the TSO DELETE command at any ISPF command line by prefixing the command with TSO:

```
tso delete 'your.zowe.proclib(zowesvr)'
```

To query which PROCLIB data set that ZOWESVR is put in, you can view the SDSF JOB log of ZOWESVR and look for the following message:

```
IEFC001I PROCEDURE ZOWESVR WAS EXPANDED USING SYSTEM LIBRARY your.zowe.proclib
```

If no ZOWESVR JOB log is available, issue the /\$D PROCLIB command at the SDSF COMMAND INPUT line and BROWSE each of the DSNAMESOME.JES.PROCLIB output lines in turn with ISPF option 1, until you find the first data set that contains member ZOWESVR. Then issue the DELETE command as shown above.

3. Remove RACF® (or equivalent) definitions using the following command:

```
RDELETE STARTED (ZOWESVR.*)  
SETR RACLIST(STARTED) REFRESH  
REMOVE (userid) GROUP(IZUUSER)
```

where *userid* indicates the user ID that is used to install Zowe.

4. Delete the z/OS® UNIX™ System Services API Mediation Layer directory and files from the API Mediation Layer installation directory using the following command:

```
rm -R /var/zowe_install_directory/api-mediation /*Zowe Installation Directory*
```

Uninstalling Zowe CLI

Important! The uninstall process does not delete the profiles and credentials that you created when using the product from your PC. To delete the profiles from your PC, delete them before you uninstall Zowe CLI.

The following steps describe how to list the profiles that you created, delete the profiles, and uninstall Zowe CLI.

Follow these steps:

1. Open a command line window.

Note: If you do not want to delete the Zowe CLI profiles from your PC, go to Step 5.

2. List all profiles that you created for a [Command Group](#) by issuing the following command:

```
zowe profiles list <profileType>
```

Example:

```
$ zowe profiles list zosmf  
The following profiles were found for the module zosmf:  
'SMITH-123' (DEFAULT)  
smith-123@SMITH-123-W7 C:\Users\SMITH-123  
$
```

3. Delete all of the profiles that are listed for the command group by issuing the following command:

Tip: For this command, use the results of the `list` command.

Note: When you issue the `delete` command, it deletes the specified profile and its credentials from the credential vault in your PC's operating system.

```
zowe profiles delete <profileType> <profileName> --force
```

Example:

```
zowe profiles delete zosmf SMITH-123 --force
```

4. Repeat Steps 2 and 3 for all Zowe CLI command groups and profiles.

5. Uninstall Zowe CLI by issuing one of the following commands:

- If you installed Zowe CLI from the package, issue the following command

```
npm uninstall --global @brightside/core
```

- If you installed Zowe CLI from the online registry, issue the following command:

```
npm uninstall --global brightside
```

The uninstall process removes all Zowe CLI installation directories and files from your PC.

6. Delete the C:\Users\<user_name>\.brightside directory on your PC. The directory contains the Zowe CLI log files and other miscellaneous files that were generated when you used the product.

Tip: Deleting the directory does not harm your PC.

7. If you installed Zowe CLI from the online registry, issue the following command to clear your scoped npm registry:

```
npm config set @brightside:registry
```

Chapter 3. Configuring Zowe

Follow these procedures to configure the components of Zowe.

Zowe Application Framework (zLUX) configuration

After you install Zowe, you can optionally configure the terminal application plug-ins or modify the Zowe Application Server (zLUX Proxy Server) and ZSS configuration, if needed.

Setting up terminal application plug-ins

Follow these optional steps to configure the default connection to open for the terminal application plug-ins.

Setting up the TN3270 mainframe terminal application plug-in

`_defaultTN3270.json` is a file in `tn3270-ng2/`, which is deployed during setup. Within this file, you can specify the following parameters to configure the terminal connection:

```
"host": <hostname>
"port": <port>
"security": {
  type: <"telnet" or "tls">
}
```

Setting up the VT Terminal application plug-in

`_defaultVT.json` is a file in `vt-ng2/`, which is deployed during setup. Within this file, you can specify the following parameters to configure the terminal connection:

```
"host":<hostname>
"port":<port>
"security": {
  type: <"telnet" or "ssh">
}
```

Configuring the zLUX Proxy Server and ZSS

Configuration file

The zLUX Proxy Server and ZSS rely on many parameters to run, which includes setting up networking, deployment directories, plug-in locations, and more.

For convenience, the zLUX Proxy Server and ZSS read from a JSON file with a common structure. ZSS reads this file directly as a startup argument, while the zLUX Proxy Server as defined in the `zlux-proxy-server` repository accepts several parameters, which are intended to be read from a JSON file through an implementer of the server, such as the example in the `zlux-example-server` repository, the `js/zluxServer.js` file. This file accepts a JSON file that specifies most, if not all, of the parameters needed. Other parameters can be provided through flags, if needed.

An example JSON file can be found in the `zlux-example-server` repository, in the `zluxserver.json` in the `config` directory.

Note: All examples are based on the *zlux-example-server* repository.

Network configuration

Note: The following attributes are to be defined in the server's JSON configuration file.

The zLUX Proxy Server can be accessed over HTTP, HTTPS, or both, provided it has been configured for either (or both).

HTTP

To configure the server for HTTP, complete these steps:

1. Define an attribute *http* within the top-level *node* attribute.
2. Define *port* within *http*. Where *port* is an integer parameter for the TCP port on which the server will listen. Specify 80 or a value between 1024-65535.

HTTPS

For HTTPS, specify the following parameters:

1. Define an attribute *https* within the top-level *node* attribute.
2. Define the following within *https*:
 - *port*: An integer parameter for the TCP port on which the server will listen. Specify 443 or a value between 1024-65535.
 - *certificates*: An array of strings, which are paths to PEM format HTTPS certificate files.
 - *keys*: An array of strings, which are paths to PEM format HTTPS key files.
 - *pfx*: A string, which is a path to a PFX file which must contain certificates, keys, and optionally Certificate Authorities.
 - *certificateAuthorities* (Optional): An array of strings, which are paths to certificate authorities files.
 - *certificateRevocationLists* (Optional): An array of strings, which are paths to certificate revocation list (CRL) files.

Note: When using HTTPS, you must specify *pfx*, or both *certificates* and *keys*.

Network example

In the example configuration, both HTTP and HTTPS are specified:

```
"node": {
  "https": {
    "port": 8544,
    //pfx (string), keys, certificates, certificateAuthorities, and certificateRevocationLists
    are all valid here.
    "keys": ["../deploy/product/ZLUX/serverConfig/server.key"],
    "certificates": ["../deploy/product/ZLUX/serverConfig/server.cert"]
  },
  "http": {
    "port": 8543
  }
}
```

Deploy configuration

When the zLUX Proxy Server is running, it accesses the server's settings and reads or modifies the contents of its resource storage. All of this data is stored within the Deploy folder hierarchy, which is spread out into a several scopes:

- **Product:** The contents of this folder are not meant to be modified, but used as defaults for a product.
- **Site:** The contents of this folder are intended to be shared across multiple zLUX Proxy Server instances, perhaps on a network drive.
- **Instance:** This folder represents the broadest scope of data within the given zLUX Proxy Server instance.
- **Group:** Multiple users can be associated into one group, so that settings are shared among them.
- **User:** When authenticated, users have their own settings and storage for the application plug-ins that they use.

These directories dictate where the [Configuration Dataservice](#) stores content.

Deploy example

```
// All paths relative to zlux-example-server/js or zlux-example-server/bin
// In real installations, these values will be configured during the installation process.
"rootDir": "../deploy",
"productDir": "../deploy/product",
"siteDir": "../deploy/site",
"instanceDir": "../deploy/instance",
"groupsDir": "../deploy/instance/groups",
"usersDir": "../deploy/instance/users"
```

Application plug-in configuration

This topic describes application plug-ins that are defined in advance.

In the configuration file, you can specify a directory that contains JSON files, which tell the server what application plug-in to include and where to find it on disk. The backend of these application plug-ins use the server's plug-in structure, so much of the server-side references to application plug-ins use the term *plug-in*.

To include application plug-ins, define the location of the plug-ins directory in the configuration file, through the top-level attribute **pluginsDir**.

Note: In this example, the directory for these JSON files is /plugins. Yet, to separate configuration files from runtime files, the `zlux-example-server` repository copies the contents of this folder into /deploy/instance/ZLUX/plugins. So, the example configuration file uses the latter directory.

Plug-ins directory example

```
// All paths relative to zlux-example-server/js or zlux-example-server/bin
// In real installations, these values will be configured during the install process.
//...
"pluginsDir": "../deploy/instance/ZLUX/plugins",
```

Logging configuration

For more information, see [Logging Utility](#).

ZSS configuration

Running ZSS requires a JSON configuration file that is similar or the same as the one used for the zLUX Proxy Server. The attributes that are needed for ZSS, at minimum, are: **rootDir**, *productDir*, *siteDir*, *instanceDir*, *groupsDir*, *usersDir*, *pluginsDir* and *zssPort*. All of these attributes have the same meaning as described above for the server, but if the zLUX Proxy Server and ZSS are not run from the same location, then these directories can be different.

The *zssPort* attribute is specific to ZSS. This is the TCP port on which ZSS listens in order to be contacted by the zLUX Proxy Server. Define this port in the configuration file as a value between 1024-65535.

Connecting the zLUX Proxy Server to ZSS

When you run the zLUX Proxy Server, specify the following flags to declare which ZSS instance the Zowe Application Framework will proxy ZSS requests to:

- *-h*: Declares the host where ZSS can be found. Use as "*-h <hostname>*"
- *-P*: Declares the port at which ZSS is listening. Use as "*-P <port>*"

Zowe Application Framework logging

The Zowe Application Framework log files contain processing messages and statistics. The log files are generated in the following default locations:

- Zowe Proxy Server: `zlux-example-server/log/nodeServer-yyyy-mm-dd-hh-mm.log`
- ZSS: `zlux-example-server/log/zssServer-yyyy-mm-dd-hh-mm.log`

The logs are timestamped in the format yyyy-mm-dd-hh-mm and older logs are deleted when a new log is created at server startup.

Controlling the logging location

The log information is written to a file and to the screen. (On Windows, logs are written to a file only.)

ZLUX_NODE_LOG_DIR and ZSS_LOG_DIR environment variables

To control where the information is logged, use the environment variable `ZLUX_NODE_LOG_DIR`, for the zLUX Proxy Server, and `ZSS_LOG_DIR`, for ZSS. While these variables are intended to specify a directory, if you specify a location that is a file name, Zowe will write the logs to the specified file instead (for example: `/dev/null` to disable logging).

When you specify the environment variables `ZLUX_NODE_LOG_DIR` and `ZSS_LOG_DIR` and you specify directories rather than files, Zowe will timestamp the logs and delete the older logs that exceed the `ZLUX_NODE_LOGS_TO_KEEP` threshold.

ZLUX_NODE_LOG_FILE and ZSS_LOG_FILE environment variables

If you set the log file name for the zLUX Proxy Server by setting the `ZLUX_NODE_LOG_FILE` environment variable, or if you set the log file for ZSS by setting the `ZSS_LOG_FILE` environment variable, there will only be one log file, and it will be overwritten each time the server is launched.

Note: When you set the `ZLUX_NODE_LOG_FILE` or `ZSS_LOG_FILE` environment variables, Zowe will not override the log names, set a timestamp, or delete the logs.

If the directory or file cannot be created, the server will run (but it might not perform logging properly).

Retaining logs

By default, the last five logs are retained. To specify a different number of logs to retain, set `ZLUX_NODE_LOGS_TO_KEEP` (zLUX Proxy Server logs) or `ZSS_LOGS_TO_KEEP` (ZSS logs) to the number of logs that you want to keep. For example, if you set `ZLUX_NODE_LOGS_TO_KEEP` to 10, when the eleventh log is created, the first log is deleted.

Configuring Zowe CLI

After you install Zowe, you can optionally perform Zowe CLI configurations.

Setting environment variables for Zowe CLI

You can set environment variables on your operating system to modify Zowe CLI behavior, such as the log level and the location of the `.brightside` directory, where the logs, profiles, and plug-ins are stored. Refer to your PC operating system documentation for information about how to set environmental variables.

Setting log levels

You can set the log level to adjust the level of detail that is written to log files:

Important! Setting the log level to TRACE or ALL might result in "sensitive" data being logged. For example, command line arguments will be logged when TRACE is set.

Environment Variable	Description	Values	Default
<code>ZOWE_APP_LOG_LEVEL</code>	Zowe CLI logging level	Log4JS log levels (OFF, TRACE, DEBUG, INFO, WARN, ERROR, FATAL)	DEBUG
<code>ZOWE_IMPERATIVE_LOG_LEVEL</code>	Imperative CLI Framework logging level	Log4JS log levels (OFF, TRACE, DEBUG, INFO, WARN, ERROR, FATAL)	DEBUG

Setting the .zowe directory

You can set the location on your PC where Zowe CLI creates the .zowe directory, which contains log files, profiles, and plug-ins for the product:

Environment Variable	Description	Values	Default
ZOWE_CLI_HOME	Zowe CLI home directory location	Any valid path on your PC	Your PC default home directory

Chapter 4. Using Zowe

After you install and start Zowe, you can perform tasks with each component. See the following sections for details.

Using the Zowe Desktop

You can use the Zowe Application Framework to create application plug-ins for the Zowe Desktop. For more information, see [Extending the Zowe Application Framework](#).

Navigating the Zowe Desktop

From the Zowe Desktop, you can access Zowe applications.

Accessing the Zowe Desktop

From a supported browser, open the Zowe Desktop at `https://myhost:httpsPort/ZLUX/plugins/com.rs.mvd/web/index.html`

where:

- *myHost* is the host on which you are running the Zowe Application Server.
- *httpsPort* is the value that was assigned to *node.https.port* in *zluxserver.json*. For example, if you run the Zowe Application Server on host *myhost* and the value that is assigned to *node.https.port* in *zluxserver.json* is 12345, you would specify `https://myhost:12345/ZLUX/plugins/com.rs.mvd/web/index.html`.

Logging in and out of the Zowe Desktop

1. To log in, enter your mainframe credentials in the **Username** and **Password** fields.
2. Press Enter. Upon authentication of your user name and password, the desktop opens.

To log out, click the the avatar in the lower right corner and click **Sign Out**.

Pinning applications to the task bar

1. Click the Start menu.
2. Locate the application you want to pin.
3. Right-click the on the application icon and select **Pin to taskbar**.

Using Explorers within the Zowe Desktop

The explorer server provides a sample web client that can be used to view and manipulate the Job Entry Subsystem (JES), data sets, z/OS UNIX System Services (USS), and System log.

The following views are available from the explorer server Web UI and are accessible via the explorer server icon located in the application draw of Zowe Desktop (Navigation between views can be performed using the menu draw located in the top left corner of the explorer server Web UI):

JES Explorer

Use this view to query JES jobs with filters, and view the related steps, files, and status. You can also purge jobs from this view.

Data set Explorer

Use this view to browse the MVS™ file system by using a high-level qualifier filter. With the Dataset Explorer, you can complete the following tasks:

- List the members of partitioned data sets.
- Create new data sets using attributes or the attributes of an existing data set ("Allocate Like").
- Submit data sets that contain JCL to Job Entry Subsystem (JES).
- Edit sequential data sets and partitioned data set members with basic syntax highlighting and content assist for JCL and REXX.
- Conduct basic validation of record length when editing JCL.
- Delete data sets and members.
- Open data sets in full screen editor mode, which gives you a fully qualified link to that file. The link is then reusable for example in help tickets.

UNIX file Explorer

Use this view to browse the USS files by using a path. With the UNIX file Explorer, you can complete the following tasks:

- List files and folders.
- Create new files and folders.
- Edit files with basic syntax highlighting and content assist for JCL and REXX.
- Delete files and folders.

Zowe Desktop application plug-ins

Application plug-ins are applications that you can use to access the mainframe and to perform various tasks. Developers can create application plug-ins using a sample application as a guide. The following application plug-ins are installed by default:

Hello World Sample

The Hello World sample application plug-in for developers demonstrates how to create a dataservice and how to create an application plug-in using Angular.

IFrame Sample

The IFrame sample application plug-in for developers demonstrates how to embed pre-made webpages within the desktop as an application and how an application can request an action of another application (see the source code for more information).

z/OS Subsystems

This z/OS Subsystems plug-in helps you find information about the important services on the mainframe, such as CICS, Db2, and IMS.

TN3270

This TN3270 plug-in provides a 3270 connection to the mainframe on which the Zowe Application Server runs.

VT Terminal

The VT Terminal plug-in provides a connection to UNIX System Services and UNIX.

API Catalog

The API Catalog plug-in lets you view API services that have been discovered by the API Mediation Layer. For more information about the API Mediation Layer, Discovery Service, and API Catalog, see [API Mediation Layer Overview](#).

Workflows

From the Workflows application plug-in you can create, manage, and use z/OSMF workflows to manage your system.

Using the Workflows application plug-in

The Workflows application plug-in is available from the Zowe Desktop Start menu. To launch Workflows, click the Start menu in the lower-left corner of the desktop and click the Workflows application plug-in icon. The **Users/Tasks Workflows** window opens.

To refresh the display, click the circular arrow in the upper right corner of the window.

Configuration

From the **Configuration** tab, you can view, add, and remove servers.

Adding a z/OSMF server

Complete these steps to add a new z/OSMF server:

1. Click the **Configuration** tab.
2. Click the plus sign (+) on the left side of the window.
3. In the **Host** field, type the name of the host.
4. In the **Port** field, type the port number.
5. Click **OK**.

To test the connection, click **Test**. When the server is online the **Online** indicator next to the server Host and Port is green.

Setting a server as the default z/OSMF server

Complete these steps to set a default z/OSMF server:

1. Click **Set as default**.
2. Enter your user ID and password.
3. Click **Sign in**.

Note: You must specify a default server.

Removing a server

To remove a server, click **x** next to the server in the list that you want to remove.

Workflows

Click the **Workflows** tab to display all workflows on the system.

Tip: To search for a particular workflow, type the search string in the search box in the upper right portion of the tab.

The following information is displayed on the **Workflows** tab.

Workflow

The name of the workflow.

Description

The description of the workflow.

Version

The version number.

Owner

The user ID of the workflow owner.

System

The system identifier.

Status

The status of the workflow (for example, **In progress**, **Completed**, and so on.)

Progress

Progress indicator.

Defining a workflow

Complete these steps to define a workflow: 1. From the **Workflows** tab, click **Action** in the upper left corner of the tab. 2. Click **New workflow**. 3. Specify the Name, Workflow definition file, System, and Owner. 4. Click **OK**.

Viewing tasks

To view your tasks, click the **My Tasks** tab. This tab displays Workflow tasks that belong to you. You can choose to view **Pending**, **Completed**, or **All** tasks. Workflows that have tasks that are assigned to you are shown on the left side of the window. For each workflow, you can click the arrow to expand or collapse the task list. Your assigned tasks display below each workflow. Hovering over each task displays more information about the task, such as the status and the owner.

Each task has a indicator of **PERFORM** (a step needs to be performed) or **CHECK** (Check the step that was performed). Clicking **CHECK** or **PERFORM** opens a work area on the right side of the window.

Note: When a task is complete, a green clipboard icon with a checkmark is displayed.

Hovering over the task description in the title bar of the work area window on the right side displays more information corresponding workflow and the step description.

Task work area

When you click **CHECK** or **PERFORM** a work area on the right side of the window is displayed.

- When you click **CHECK**, you can view the JESMSG LG, JESJCL, JESYSMSG, or SYSTSPRT that is associated with the selected task.
- When you click **PERFORM**, you can use the work area to perform the steps associated with the selected task. Click **Next** to advance to the next step for the task.

Viewing warnings

Click the **Warnings** tab to view any warning messages that were encountered.

The following information is displayed on the **Warnings** tab.

Message Code

The message code that is associated with the warning.

Description

A description of the warning.

Date

The date of the warning.

Corresponding Workflow

The workflow that is associated with the warning.

Using APIs

Access and modify your z/OS resources such as jobs, data sets, z/OS UNIX System Services files by using APIs.

Using explorer server REST APIs

Explorer server REST APIs provide a range of REST APIs through a Swagger defined description, and a simple interface to specify API endpoint parameters and request bodies along with the response body and return code. With explorer server REST APIs, you can see the available API endpoints and try the endpoints within a browser. Swagger documentation is available from an Internet browser with a URL, for example, <https://your.host:atlas-port/ibm/api/explorer>.

Data set APIs

Use data set APIs to create, read, update, delete, and list data sets. See the following table for the operations available in data set APIs and their descriptions and prerequisites.

REST API	Description	Prerequisite
GET /api/v1/datasets/{filter}	Get a list of data sets by filter. Use this API to get a starting list of data sets, for example, userid.** .	z/OSMF restfiles
GET /api/v1/datasets/{dsn}/attributes	Retrieve attributes of a data set(s). If you have a data set name, use this API to determine attributes for a data set name. For example, it is a partitioned data set.	z/OSMF restfiles
GET /api/v1/datasets/{dsn}/members	Get a list of members for a partitioned data set. Use this API to get a list of members of a partitioned data set.	z/OSMF restfiles
GET /api/v1/datasets/{dsn}/content	Read content from a data set or member. Use this API to read the content of a sequential data set or partitioned data set member. Or use this API to return a checksum that can be used on a subsequent PUT request to determine if a concurrent update has occurred.	z/OSMF restfiles
PUT /api/v1/datasets/{dsn}/content	Write content to a data set or member. Use this API to write content to a sequential data set or partitioned data set member. If a checksum is passed and it does not match the checksum that is returned by a previous GET request, a concurrent update has occurred and the write fails.	z/OSMF restfiles
POST /api/v1/datasets/{dsn}	Create a data set. Use this API to create a data set according to the attributes that are provided. The API uses z/OSMF to create the data set and uses the syntax and rules that are described in the z/OSMF Programming Guide .	z/OSMF restfiles

REST API	Description	Prerequisite
POST /api/v1/datasets/{dsn}/{basedsn}	Create a data set by using the attributes of a given base data set. When you do not know the attributes of a new data set, use this API to create a new data set by using the same attributes as an existing one.	z/OSMF
DELETE /api/v1/datasets/{dsn}	Delete a data set or member. Use this API to delete a sequential data set or partitioned data set member.	z/OSMF restfiles

Job APIs

Use Jobs APIs to view the information and files of jobs, and submit and cancel jobs. See the following table for the operations available in Job APIs and their descriptions and prerequisites.

REST API	Description	Prerequisite
GET /api/v1/jobs	Get a list of jobs. Use this API to get a list of job names that match a given prefix, owner, or both.	z/OSMF restjobs
GET /api/v1/jobs/{jobName}/ids	Get a list of job identifiers for a given job name. If you have a list of existing job names, use this API to get a list of job instances for a given job name.	z/OSMF restjobs
GET /api/v1/jobs/{jobName}/ids/{jobId}/steps	Get job steps for a given job. With a job name and job ID, use this API to get a list of the job steps, which includes the step name, the executed program, and the logical step number.	z/OSMF restjobs
GET /api/v1/jobs/{jobName}/ids/{jobId}/steps/{stepNumber}/dds	Get data set definitions (DDs) for a given job step. If you know a step number for a given job instance, use this API to get a list of the DDs for a given job step, which includes the DD name, the data sets that are described by the DD, the original DD JCL, and the logical order of the DD in the step.	z/OSMF restjobs
GET /api/v1/jobs/{jobName}/ids/{jobId}/files	Get a list of output file names for a job. Job output files have associated DSIDs. Use this API to get a list of the DSIDs and DD name of a job. You can use the DSIDs and DD name to read specific job output files.	z/OSMF restjobs

REST API	Description	Prerequisite
GET /api/v1/jobs/{jobName}/ids/{jobId}/files/{fileId}	Read content from a specific job output file. If you have a DSID or field for a given job, use this API to read the output file's content.	z/OSMF restjobs
GET /api/v1/jobs/{jobName}/ids/{jobId}/files/{fileId}/tail	Read the tail of a job's output file. Use this API to request a specific number of records from the tail of a job output file.	z/OSMF restjobs
GET /api/v1/jobs/{jobName}/ids/{jobId}/subsystem	Get the subsystem type for a job. Use this API to determine the subsystem that is associated with a given job. The API examines the JCL of the job to determine if the executed program is CICS®, Db2®, IMS™, or IBM® MQ.	z/OSMF restjobs
POST /api/v1/jobs	Submit a job and get the job ID back. Use this API to submit a partitioned data set member or UNIX™ file.	z/OSMF restjobs
DELETE /api/v1/jobs/{jobName}/{jobId}	Cancel a job and purge its associated files. Use this API to purge a submitted job and the logged output files that it creates to free up space.	z/OSMF Running Common Information Model (CIM) server

System APIs

Use System APIs to view the version of explorer server. See the following table for available operations and their descriptions and prerequisites.

REST API	Description	Prerequisite
GET /api/v1/system/version	Get the current explorer server version. Use this API to get the current version of the explorer server microservice.	None

USS File APIs

Use USS File APIs to create, read, update, and delete USS files. See the following table for the available operations and their descriptions and prerequisites.

REST API	Description	Prerequisite
POST /api/v1/uss/files	Use this API to create new USS directories and files.	z/OSMF restfiles
DELETE /api/v1/uss/files{path}	Use this API to delete USS directories and files.	z/OSMF resfiles
GET /api/v1/files/{path}	Use this API to get a list of files in a USS directory along with their attributes.	z/OSMF restfiles
GET /api/v1/files/{path}/content	Use this API to get the content of a USS file.	z/OSMF restfiles

REST API	Description	Prerequisite
PUT /api/v1/files/{path}/content	Use this API to update the content of a USS file.	z/OSMF resfiles

z/OS System APIs

Use z/OS system APIs to view information about PARMLIB, SYSPLEX, and USER. See the following table for available operations and their descriptions and prerequisites.

REST API	Description	Prerequisite
GET /api/v1/zos/parmlib	Get system PARMLIB information. Use this API to get the PARMLIB data set concatenation of the target z/OS system.	None
GET /api/v1/zos/sysplex	Get target system sysplex and system name. Use this API to get the system and sysplex names.	None
GET /api/v1/zos/username	Get current userid. Use this API to get the current user ID.	None

Programming explorer server REST APIs

You can program explorer server REST APIs by referring to the examples in this section.

Sending a GET request in Java

Here is sample code to send a GET request to explorer server in Java™.

```
public class JobListener implements Runnable {

    /*
     * Perform an HTTPS GET at the given jobs URL and credentials
     * targetURL e.g "https://host:port/api/v1/jobs?owner=IBMU&prefix=*"
     * credentials in the form of base64 encoded string of user:password
     */
    private String executeGET(String targetURL, String credentials) {
        HttpURLConnection connection = null;
        try {
            //Create connection
            URL url = new URL(targetURL);
            connection = (HttpURLConnection) url.openConnection();
            connection.setRequestMethod("GET");
            connection.setRequestProperty("Authorization", credentials);

            //Get Response
            InputStream inputStream = connection.getInputStream();
            BufferedReader bufferedReader = new BufferedReader(new
InputStreamReader(inputStream));
            StringBuilder response = new StringBuilder();
            String line;

            //Process the response line by line
            while ((line = bufferedReader.readLine()) != null) {
                System.out.println(line);
            }

            //Cleanup
            bufferedReader.close();

            //Return the response message
            return response.toString();
        } catch (Exception e) {
            //handle any error(s)
        } finally {
            //Cleanup
            if (connection != null) {

```

```

        connection.disconnect();
    }
}
}

```

Sending a GET request in JavaScript

Here is sample code written in JavaScript™ using features from ES6 to send a GET request to explorer server.

```

const BASE_URL = 'hostname.com:port/api/v1';

// Call the jobs GET api to get all jobs with the userID IBMUSER
function getJobs(){
    let parameters = "prefix=*&owner=IBMUSER";
    let contentURL = `${BASE_URL}/jobs?${parameters}`;
    let result = fetch(contentURL, {credentials: "include"})
        .then(response => response.json())
        .catch((e) => {
            //handle any error
            console.log("An error occurred: " + e);
        });
    return result;
}

```

Sending a POST request in JavaScript

Here is sample code written in JavaScript™ using features from ES6 to send a POST request to explorer server.

```

// Call the jobs POST api to submit a job from a data set (ATLAS.TEST.JCL(TSTJ0001))

function submitJob(){
    let payload = "{\"file\":\"'ATLAS.TEST.JCL(TSTJ0001)'\":\"\"}";
    let contentURL = `${BASE_URL}/jobs`;
    let result = fetch(contentURL,
        {
            credentials: "include",
            method: "POST",
            body: payload
        })
        .then(response => response.json())
        .catch((e) => {
            //handle any error
            console.log("An error occurred: " + e);
        });
    return result;
}

```

Extended API sample in JavaScript

Here is an extended API sample that is written using JavaScript™ with features from ES62015 (map).

```

////////////////////////////////////
// Extended API Sample
// This Sample is written using Javascript with features from ES62015 (map).
// The sample is also written using JSX giving the ability to return HTML elements
// with Javascript variables embedded. This sample is based upon the codebase of the
// sample UI (see- hostname:port/explorer-mvs) which is written using Facebook's React, Redux,
// Router and Google's material-ui
////////////////////////////////////

// Return a table with rows detailing the name and jobID of all jobs matching
// the specified parameters
function displayJobNamesTable(){
    let jobsJSON = getJobs("*", "IBMUSER");
    return (<table>
        {jobsJSON.map(job => {
            return <tr><td>{job.name}</td><td>{job.id}</td></tr>
        })}
        </table>);
}

// Call the jobs GET api to get all jobs with the userID IBMUSER

```

```
function getJobs(owner, prefix){
  const BASE_URL = 'hostname.com:port/api/v1';
  let parameters = "prefix=" + prefix + "&owner=" + owner;
  let contentURL = `${BASE_URL}/jobs?${parameters}`;
  let result = fetch(contentURL, {credentials: "include"})
    .then(response => response.json())
    .catch((e) => {
      //handle any error
      console.log("An error occurred: " + e);
    });
  return result;
}
```

Using explorer server WebSocket services

The explorer server provides WebSocket services that can be accessed by using the WSS scheme. With explorer server WebSocket services, you can view the system log in the System log UI that is refreshed automatically when messages are written. You can also open a JES spool file for an active job and view its contents that refresh through a web socket.

Server Endpoint	Description	Prerequisites
/api/sockets/jobs/{jobname}/ids/{jobid}/files/{fileid}	Tail the output of an active job. Use this WSS endpoint to read the tail of an active job's output file in real time.	z/OSMF restjobs

API Catalog

As an application developer, use the API Catalog to view what services are running in the API Mediation Layer. Through the API Catalog, you can also view the associated API documentation corresponding to a service, descriptive information about the service, and the current state of the service. The tiles in the API Catalog can be customized by changing values in the `mfaas.catalog-ui-tile` section defined in the `application.yml` of a service. A microservice that is onboarded with the API Mediation Layer and configured appropriately, registers automatically with the API Catalog and a tile for that service is added to the Catalog.

Note: For more information about how to configure the API Catalog in the `application.yml`, see: [Add API Onboarding Configuration](#).

View Service Information and API Documentation in the API Catalog

Use the API Catalog to view services, API documentation, descriptive information about the service, the current state of the service, service endpoints, and detailed descriptions of these endpoints.

Note: Verify that your service is running. At least one started and registered instance with the Discovery Service is needed for your service to be visible in the API Catalog.

Follow these steps:

1. Use the search bar to find the service that you are looking for. Services that belong to the same product family are displayed on the same tile.

Example: Sample Applications, Endeavor, SDK Application

2. Click the tile to view header information, the registered services under that family ID, and API documentation for that service.

Notes:

- The state of the service is indicated in the service tile on the dashboard page. If no instances of the service are currently running, the tile displays a message that no services are running.
- At least one instance of a service must be started and registered with the discovery service for it to be visible in the API Catalog. If the service that you are onboarding is running, and the corresponding

API documentation is displayed, this API documentation is cached and remains visible even when the service and all service instances stop.

- Descriptive information about the service and a link to the home page of the service is displayed.

Example:

The screenshot shows the API Catalog interface. At the top, there's a blue header with the 'API Catalog' logo. Below it, a breadcrumb trail shows '< Back'. The main heading is 'Sample API Mediation Layer Applications', with a subtitle 'Applications which demonstrate how to make a service integrated to the API Mediation Layer ecosystem'. A navigation bar contains three tabs: 'discoverableclient', 'sampleservice', and 'enablerv1sampleapp'. The 'enablerv1sampleapp' tab is selected. The main content area displays the title 'Service Integration Enabler V2 Sample Application (Spring Boot 2.x)', followed by 'API Doc Version: 1.0.0' and a base URL. A description states it's a 'Sample service showing how to integrate a Spring Boot v2.x application'. Below this, there's a section for 'Other Operations' with a dropdown arrow. A 'GET' button is visible, followed by the endpoint path '/api/v1/discoverableclient/api/v1/instance/gateway-uri' and a note 'What is the URI of the Gateway'.

3. Expand the endpoint panel to see a detailed summary with responses and parameters of each endpoint, the endpoint description, and the full structure of the endpoint.

Example:

The screenshot shows the API Catalog interface for the 'Service Integration Enabler V1 Sample App (spring boot 1.x)'. The title is 'Service Integration Enabler V1 Sample App (spring boot 1.x)', with 'API Doc Version: 1.0.0' and a base URL. The description is 'Sample micro-service showing how to enable a Spring Boot v1.x application'. Below this, there's a section for 'V1EnablerSampleApp Sample Controller' with a dropdown arrow. A 'GET' button is visible, followed by the endpoint path '/api/v1/enablerv1sampleapp/samples' and a note 'Retrieve all samples'. The endpoint panel is expanded, showing a description: 'Simple method to demonstrate how to expose an API endpoint with Open API information'. Below this, there's a 'Parameters' section with 'No parameters'. The 'Responses' section is expanded, showing a list of response codes and their descriptions. The 'Response content type' is set to 'application/json'. The responses are:

Response code	Description
200	OK
401	Unauthorized
403	Forbidden
404	URI not found
500	Internal Error

Notes:

- If a lock icon is visible on the right side of the endpoint panel, the endpoint requires authentication.

- The structure of the endpoint is displayed relative to the base URL.
- The URL path of the abbreviated endpoint relative to the base URL is displayed in the following format:

Example:

```
/api/v1/{yourServiceId}/{endpointName}
```

The path of the full URL that includes the base URL is also displayed in the following format:

```
https://hostName:basePort/api/v1/{yourServiceId}/{endpointName}
```

Both links target the same endpoint location.

Using Zowe CLI

This section contains the following articles about using Zowe CLI.

Display Zowe CLI help

Zowe CLI contains a help system that is embedded directly into the command-line interface. When you want help with Zowe CLI, you issue help commands that provide you with information about the product, syntax, and usage.

Display top-level help

To begin using the product, open a command line window and issue the following command to view the top-level help descriptions:

```
zowe --help
```

Tip: The command `zowe` initiates the product on a command line. All Zowe CLI commands begin with `zowe`.

Help structure

The help displays the following types of information:

- **Description:** An explanation of the functionality for the command group, action, or option that you specified in a `--help` command.
- **Usage:** The syntax for the command. Refer to usage to determine the expected hierarchical structure of a command.
- **Options:** Flags that you can append to the end of a command to specify particular values or booleans. For example, the volume size for a data set that you want to create.
- **Global Options:** Flags that you can append to any command in Zowe CLI. For example, the `--help` flag is a global option.

Displaying command group, action, and object help

You can use the `--help` global option to get more information about a specific command group, action, or object. Use the following syntax to display group-level help and learn more about specific command groups (for example, `zos-jobs` and `zos-files`):

```
zowe <group, action, or object name> --help
```

```
zowe zos-files create --help
```

Zowe CLI command groups

Zowe CLI contains command groups that focus on specific business processes. For example, the `zos-files` command group provides the ability to interact with mainframe data sets. This article provides you with a brief synopsis of the tasks that you can perform with each group. For more information, see [Display Zowe CLI Help](#).

The commands available in the product are organized in a hierarchical structure. Command groups (for example, `zos-files`) contain actions (for example, `create`) that let you perform actions on specific objects (for example, a specific type of data set). For each action that you perform on an object, you can specify options that affect the operation of the command.

Important! Before you issue these commands, verify that you completed the steps in [Create a Zowe CLI profile](#) and [Test Connection to z/OSMF](#) to help ensure that Zowe CLI can communicate with z/OS systems.

Zowe CLI contains the following command groups:

plugins

The `plugins` command group lets you install and manage third-party plug-ins for the product. Plug-ins extend the functionality of Zowe CLI in the form of new commands.

With the `plugins` command group, you can perform the following tasks:

- Install or uninstall third-party plug-ins.
- Display a list of installed plug-ins.
- Validate that a plug-in integrates with the base product properly.

Note: For more information about `plugins` syntax, actions, and options, open Zowe CLI and issue the following command:

```
zowe plugins -h
```

profiles

The `profiles` command group lets you create and manage profiles for use with other Zowe CLI command groups. Profiles allow you to issue commands to different mainframe systems quickly, without specifying your connection details with every command.

With the `profiles` command group, you can perform the following tasks:

- Create, update, and delete profiles for any Zowe CLI command group that supports profiles.
- Set the default profile to be used within any command group.
- List profile names and details for any command group, including the default active profile.

Note: For more information about `profiles` syntax, actions, and options, open Zowe CLI, and issue the following command:

```
zowe profiles -h
```

provisioning

The `provisioning` command group lets you perform IBM z/OSMF provisioning tasks with templates and provisioned instances from Zowe CLI.

With the `provisioning` command group, you can perform the following tasks:

- Provision cloud instances using z/OSMF Software Services templates.
- List information about the available z/OSMF Service Catalog published templates and the templates that you used to publish cloud instances.
- List summary information about the templates that you used to provision cloud instances. You can filter the information by application (for example, DB2 and CICS) and by the external name of the provisioned instances.

- List detail information about the variables used (and their corresponding values) on named, published cloud instances.

Note: For more information about provisioning syntax, actions, and options, open Zowe CLI and issue the following command:

```
zowe provisioning -h
```

zos-console

The zos-console command group lets you issue commands to the z/OS console by establishing an extended Multiple Console Support (MCS) console.

With the zos-console command group, you can perform the following tasks: **Important!** Before you issue z/OS console commands with Zowe CLI, security administrators should ensure that they provide access to commands that are appropriate for your organization. - Issue commands to the z/OS console. - Collect command responses and continue to collect solicited command responses on-demand.

Note: For more information about zos-console syntax, actions, and options, open Zowe CLI and issue the following command:

```
zowe zos-console -h
```

zos-files

The zos-files command group lets you interact with data sets on z/OS systems.

With the zos-files command group, you can perform the following tasks:

- Create partitioned data sets (PDS) with members, physical sequential data sets (PS), and other types of data sets from templates. You can specify options to customize the data sets you create.
- Download mainframe data sets and edit them locally in your preferred Integrated Development Environment (IDE).
- Upload local files to mainframe data sets.
- List available mainframe data sets.
- Interact with VSAM data sets directly, or invoke Access Methods Services (IDCAMS) to work with VSAM data sets.

Note: For more information about zos-files syntax, actions, and options, open Zowe CLI and issue the following command:

```
zowe zos-files -h
```

zos-jobs

The zos-jobs command group lets you submit jobs and interact with jobs on z/OS systems.

With the zos-jobs command group, you can perform the following tasks:

- Submit jobs from JCL that resides on the mainframe or a local file.
- List jobs and spool files for a job.
- View the status of a job or view a spool file from a job.

Note: For more information about zos-jobs syntax, actions, and options, open Zowe CLI and issue the following command:

```
zowe zos-jobs -h
```

zos-tso

The zos-tso command group lets you issue TSO commands and interact with TSO address spaces on z/OS systems.

With the zos-tso command group, you can perform the following tasks:

- Execute REXX scripts
- Create a TSO address space and issue TSO commands to the address space.
- Review TSO command response data in Zowe CLI.

Note: For more information about zos-tso syntax, actions, and options, open Zowe CLI and issue the following command:

```
zowe zos-tso -h
```

zosmf

The zosmf command group lets you work with Zowe CLI profiles and get general information about z/OSMF.

With the zosmf command group, you can perform the following tasks:

- Create and manage your Zowe CLI zosmf profiles. You must have at least one zosmf profile to issue most commands. Issue the `zowe help explain profiles` command in Zowe CLI to learn more about using profiles.
- Verify that your profiles are set up correctly to communicate with z/OSMF on your system. For more information, see [Test Connection to z/OSMF](#).
- Get information about the current z/OSMF version, host, port, and plug-ins installed on your system.

Note: For more information about zosmf syntax, actions, and options, open Zowe CLI and issue the following command:

```
zowe zosmf -h
```

VSCode Extension for Zowe

The Visual Studio Code (VSCode) Extension for Zowe lets you interact with data sets that are stored on IBM z/OS mainframe. Install the extension directly to VSCode to enable the extension within the GUI. You can explore data sets, view their contents, make changes, and upload the changes to the mainframe. For some users, it can be more convenient to interact with data sets through a GUI rather than using command-line interfaces or 3270 emulators. The extension is powered by Zowe CLI.

Note: The primary documentation, for this plug-in is available on the [Visual Studio Code Marketplace](#). This topic is intended to be an overview of the extension.

- [Prerequisites](#)
- [Installing](#)
- [Use Cases](#)

Prerequisites

Before you use the VSCode extension, meet the following prerequisites on your PC:

- Install [VSCode](#).
- Install [Zowe CLI](#).
- Create at least one Zowe CLI 'zosmf' profile so that the extension can communicate with the mainframe. See [Creating a Zowe CLI Profile](#).

Installing

1. Address [the prerequisites](#).
2. Open VSCode. Navigate to the **Extensions** tab on the left side of the UI.

3. Click the green **Install** button to install the plug-in.
4. Restart VSCode. The plug-in is now installed and available for use.

Tip: For information about how to install the extension from a VSIX file and run system tests on the extension, see the Developer README file in the Zowe VSCode extension GitHub repository.

Use-Cases

As an developer, you can use VSCode Extension for Zowe to perform the following tasks.

- View and filter mainframe data sets.
- Create download, edit, upload, and delete PDS and PDS members.
- Use "safe save" to safely resolve conflicts when a data set is changed during local editing.
- Switch between Zowe CLI profiles to quickly target different mainframe systems.

Note: For detailed step-by-step instructions for using the plug-in and more information about each feature, see [Zowe on the Visual Studio Code Marketplace](#).

Chapter 5. Extending the Zowe Application Framework (zLUX)

You can create plug-ins to extend the capabilities of the Zowe Application Framework.

Creating application plug-ins

An application plug-in is an installable set of files that present resources in a web-based user interface, as a set of RESTful services, or in a web-based user interface and as a set of RESTful services.

Before you build an application plug-in, you must set the UNIX environment variables that support the plug-in environment.

Setting the environment variables for plug-in development

To set up the environment, the node must be accessible on the PATH. To determine if the node is already on the PATH, issue the following command from the command line:

```
node --version
```

If the version is returned, the node is already on the PATH.

If nothing is returned from the command, you can set the PATH using the *NODE_HOME* variable. The *NODE_HOME* variable must be set to the directory of the node install. You can use the `export` command to set the directory. For example:

```
export NODE_HOME=node_installation_directory
```

Using this directory, the node will be included on the PATH in `nodeServer.sh`. (`nodeServer.sh` is located in `zlux-example-server/bin`).

Using the sample application plug-in

You can experiment with the sample application plug-in called `sample-app` that is provided.

To build the sample application plug-in, `node` and `npm` must be included in the PATH. You can use the `npm run build` or `npm start` command to build the sample application plug-in. These commands are configured in `package.json`.

Note:

- If you change the source code for the sample application, you must rebuild it.
- If you want to modify `sample-app`, you must run `_npm install_` in the Zowe Desktop and the `sample-app/webClient`. Then, you can run `_npm run build_` in `sample-app/webClient`.
- Ensure that you set the `MVD_DESKTOP_DIR` system variable to the Zowe Desktop plug-in location. For example: `<ZLUX_CAP>/zlux-app-manager/virtual-desktop`.

1. Add an item to `sample-app`. The following figure shows an excerpt from `app.component.ts`:

```
export class AppComponent { items = ['a', 'b', 'c', 'd'] title = 'app';  
helloText: string; serverResponseMessage: string;
```

2. Save the changes to `app.component.ts`.

3. Issue one of the following commands:

- To rebuild the application plug-in, issue the following command: `npm run build`

- To rebuild the application plug-in and wait for additional changes to `app.component.ts`, issue the following command: `npm start`
4. Reload the web page.
 5. If you make changes to the sample application source code, follow these steps to rebuild the application:
 - a. Navigate to the `sample-app` subdirectory where you made the source code changes.
 - b. Issue the following command: `npm run build`
 - c. Reload the web page.

zLUX plug-ins definition and structure

The zLUX Application Server (`zlux-proxy-server`) enables extensibility with application plug-ins. Application plug-ins are a subcategory of the unit of extensibility in the server called a *plug-in*.

The files that define a plug-in are located in the `pluginsDir` directory.

Application plug-in filesystem structure

An application plug-in can be loaded from a filesystem that is accessible to the zLUX Application Server, or it can be loaded dynamically at runtime. When accessed from a filesystem, there are important considerations for the developer and the user as to where to place the files for proper build, packaging, and operation.

Root files and directories

The root of an application plug-in directory contains the following files and directories.

pluginDefinition.json

This file describes an application plug-in to the zLUX Application Server. (A plug-in is the unit of extensibility for the zLUX Application Server. An application plug-in is a plug-in of the type "Application", the most common and visible type of plug-in.) A definition file informs the server whether the application plug-in has server-side dataservices, client-side web content, or both.

Dev and source content

Aside from demonstration or open source application plug-ins, the following directories should not be visible on a deployed server because the directories are used to build content and are not read by the server.

nodeServer

When an application plug-in has router-type dataservices, they are interpreted by the zLUX Application Server by attaching them as ExpressJS routers. It is recommended that you write application plug-ins using Typescript, because it facilitates well-structured code. Use of Typescript results in build steps because the pre-transpilation Typescript content is not to be consumed by NodeJS. Therefore, keep server-side source code in the `nodeServer` directory. At runtime, the server loads router dataservices from the `lib` directory.

webClient

When an application plug-in has the *webContent* attribute in its definition, the server serves static content for a client. To optimize loading of the application plug-in to the user, use Typescript to write the application plug-in and then package it using Webpack. Use of Typescript and Webpack result in build steps because the pre-transpilation Typescript and the pre-webpack content are not to be consumed by the browser. Therefore, separate the source code from the served content by placing source code in the `webClient` directory.

Runtime content

At runtime, the following set of directories are used by the server and client.

lib

The `lib` directory is where router-type dataservices are loaded by use in the zLUX Application Server. If the JS files that are loaded from the `lib` directory require NodeJS modules, which are not provided by the server base (the modules `ZLUX-proxy-server` requires are added to `NODE_PATH` at runtime), then you must include these modules in `lib/node_modules` for local directory lookup or ensure that they are found on the `NODE_PATH` environment variable. `nodeServer/node_modules` is not automatically accessed at runtime because it is a dev and build directory.

web

The `web` directory is where the server serves static content for an application plug-in that includes the `webContent` attribute in its definition. Typically, this directory contains the output of a webpack build. Anything you place in this directory can be accessed by a client, so only include content that is intended to be consumed by clients.

Location of plug-in files

The files that define a plug-in are located in the `pluginsDir` directory.

pluginsDir directory

At startup, the server reads from the `pluginsDir` directory. The server loads the valid plug-ins that are found by the information that is provided in the JSON files.

Within the `pluginsDir` directory are a collection of JSON files. Each file has two attributes, which serve to locate a plug-in on disk:

location: This is a directory path that is relative to the server's executable (such as `zlux-example-server/bin/nodeServer.sh`) at which a `pluginDefinition.json` file is expected to be found.

identifier: The unique string (commonly styled as a Java resource) of a plug-in, which must match what is in the `pluginDefinition.json` file.

Plug-in definition file

`pluginDefinition.json` is a file that describes a plug-in. Each plug-in requires this file, because it defines how the server will register and use the backend of an application plug-in (called a *plug-in* in the terminology of the proxy server). The attributes in each file are dependent upon the `pluginType` attribute. Consider the following `pluginDefinition.json` file from `sample-app`:

```
{
  "identifier": "com.rs.mvd.myplugin",
  "apiVersion": "1.0",
  "pluginVersion": "1.0",
  "pluginType": "application",
  "webContent": {
    "framework": "angular2",
    "launchDefinition": {
      "pluginShortNameKey": "helloWorldTitle",
      "pluginShortNameDefault": "Hello World",
      "imageSrc": "assets/icon.png"
    },
    "descriptionKey": "MyPluginDescription",
    "descriptionDefault": "Base MVD plugin template",
    "isSingleWindowApp": true,
    "defaultWindowStyle": {
      "width": 400,
      "height": 300
    }
  },
  "dataServices": [
    {
      "type": "router",
      "name": "hello",
    }
  ]
}
```

```

    "serviceLookupMethod": "external",
    "fileName": "helloWorld.js",
    "routerFactory": "helloWorldRouter",
    "dependenciesIncluded": true
  }
}

```

Plug-in attributes

There are two categories of attributes: General and Application.

General attributes

identifier

Every application plug-in must have a unique string ID that associates it with a URL space on the server.

apiVersion

The version number for the pluginDefinition scheme and application plug-in or dataservice requirements. The default is 1.0.0.

pluginVersion

The version number of the individual plug-in.

pluginType

A string that specifies the type of plug-in. The type of plug-in determines the other attributes that are valid in the definition.

- **application:** Defines the plug-in as an application plug-in. Application plug-ins are composed of a collection of web content for presentation in the zLUX web component (such as the Zowe Desktop), or a collection of dataservices (REST and websocket), or both.
- **library:** Defines the plug-in as a library that serves static content at a known URL space.
- **node authentication:** Authentication and Authorization handlers for the zLUX Application Server.

Application attributes

When a plug-in is of *pluginType* application, the following attributes are valid:

webContent

An object that defines several attributes about the content that is shown in a web UI.

dataServices

An array of objects that describe REST or websocket dataservices.

configurationData

An object that describes the resource structure that the application plug-in uses for storing user, group, and server data.

Application web content attributes

An application that has the *webContent* attribute defined provides content that is displayed in a zLUX web UI.

The following attributes determine some of this behavior:

framework

States the type of web framework that is used, which determines the other attributes that are valid in *webContent*.

- **angular2:** Defines the application as having an Angular (2+) web framework component. This is the standard for a "native" framework zLUX application.

- **iframe:** Defines the application as being external to the native zLUX web application environment, but instead embedded in an iframe wrapper.

launchDefinition

An object that details several attributes for presenting the application in a web UI.

- **pluginShortNameDefault:** A string that gives a name to the application when `i18n` is not present. When `i18n` is present, `i18n` is applied by using the `pluginShortNameKey`.
- **descriptionDefault:** A longer string that specifies a description of the application within a UI. The description is seen when `i18n` is not present. When `i18n` is present, `i18n` is applied by using the `descriptionKey`.
- **imageSrc:** The relative path (from `/web`) to a small image file that represents the application icon.

defaultWindowStyle

An object that details the placement of a default window for the application in a web UI.

- **width:** The default width of the application plug-in window, in pixels.
- **height:** The default height of the application plug-in window, in pixels.

IFrame application web content

In addition to the general web content attributes, when the framework of an application is "iframe", you must specify the page that is being embedded in the iframe. To do so, include the attribute `startingPage` within `webContent`. `startingPage` is relative to the application's `/web` directory.

Specify `startingPage` as a relative path rather than an absolute path because the `pluginDefinition.json` file is intended to be read-only, and therefore would not work well when the hostname of a page changes.

Within an IFrame, the application plug-in still has access to the globals that are used by zLUX for application-to-application communication; simply access `window.parent.RocketMVD`.

zLUX dataservices

Dataservices are a dynamic component of the backend of a zLUX application. Dataservices are optional, because the proxy server might only serve static content for a particular application. However, when included in an application, a dataservice defines a URL space for which the server will run the extensible code from the application. Dataservices are primarily intended to be used to create REST APIs and Websocket channels.

Defining a dataservice

Within the `sample-app` repository, in the top directory, you will find a `pluginDefinition.json` file. Each zLUX application requires this file, because it defines how the server registers and uses the backend of an application (called a plug-in in the terminology of the proxy server).

Within the JSON file, there is a top level attribute, `dataServices`:

```
"dataServices": [
  {
    "type": "router",
    "name": "hello",
    "serviceLookupMethod": "external",
    "fileName": "helloWorld.js",
    "routerFactory": "helloWorldRouter",
    "dependenciesIncluded": true
  }
]
```

Dataservices defined in pluginDefinition

The following attributes are valid for each dataservice in the `dataServices` array:

type

Specify one of the following values:

- **router**: Router dataservices are dataservices that run under the proxy server, and use ExpressJS Routers for attaching actions to URLs and methods.
- **service**: Service dataservices are dataservices that run under ZSS, and utilize the API of ZSS dataservices for attaching actions to URLs and methods.

name

The name of the service that must be unique for each `pluginDefinition.json` file. The name is used to reference the dataservice during logging and it is also used in the construction of the URL space that the dataservice occupies.

serviceLookupMethod

Specify `external` unless otherwise instructed.

fileName

The name of the file that is the entry point for construction of the dataservice, relative to the application's `/lib` directory. In the case of `sample-app`, upon transpilation of the typescript code, javascript files are placed into the `/lib` directory.

routerFactory (Optional)

When you use a router dataservice, the dataservice is included in the proxy server through a `require()` statement. If the dataservice's exports are defined such that the router is provided through a factory of a specific name, you must state the name of the exported factory using this attribute.

dependenciesIncluded

Must be `true` for anything in the `pluginDefinition.json` file. (This setting is false only when adding dataservices to the server dynamically.)

Dataservice API

The API for a dataservice can be categorized as Router-based or ZSS-based, and Websocket or not.

Note: Each Router dataservice can safely import `express`, `express-ws`, and `bluebird` without requiring the modules to be present, because these modules exist in the proxy server's directory and the `NODE_MODULES` environment variable can include this directory.

Router-based dataservices

HTTP/REST router dataservices

Router-based dataservices must return a (bluebird) Promise that resolves to an ExpressJS router upon success. For more information, see the ExpressJS guide on use of Router middleware: [Using Router Middleware](#).

Because of the nature of Router middleware, the dataservice need only specify URLs that stem from a root `'/'` path, as the paths specified in the router are later prepended with the unique URL space of the dataservice.

The Promise for the Router can be within a Factory export function, as mentioned in the `pluginDefinition` specification for *routerFactory* above, or by the module constructor.

An example is available in `sample-app/nodeServer/ts/helloWorld.ts`

Websocket router dataservices

ExpressJS routers are fairly flexible, so the contract to create the Router for Websockets is not significantly different.

Here, the `express-ws` package is used, which adds websockets through the `ws` package to ExpressJS. The two changes between a websocket-based router and a normal router are that the method is `'ws'`, as in `router.ws(<url>, <callback>)`, and the callback provides the websocket on which you must define event listeners.

See the `ws` and `express-ws` topics on www.npmjs.com for more information about how they work, as the API for websocket router dataservices is primarily provided in these packages.

An example is available in `zlux-proxy-server/plugins/terminal-proxy/lib/terminalProxy.js`

Router dataservice context

Every router-based dataservice is provided with a `Context` object upon creation that provides definitions of its surroundings and the functions that are helpful. The following items are present in the `Context` object:

serviceDefinition

The dataservice definition, originally from the `pluginDefinition.json` file within a plug-in.

serviceConfiguration

An object that contains the contents of configuration files, if present.

logger

An instance of a zLUX Logger, which has its component name as the unique name of the dataservice within a plug-in.

makeSublogger

A function to create a zLUX Logger with a new name, which is appended to the unique name of the dataservice.

addBodyParseMiddleware

A function that provides common body parsers for HTTP bodies, such as JSON and plaintext.

plugin

An object that contains more context from the plug-in scope, including:

- **pluginDef:** The contents of the `pluginDefinition.json` file that contains this dataservice.
- **server:** An object that contains information about the server's configuration such as:
 - **app:** Information about the product, which includes the *productCode* (for example: ZLUX).
 - **user:** Configuration information of the server, such as the port on which it is listening.

Zowe Desktop and window management

The Zowe Desktop is a web component of Zowe, which is an implementation of `MVDWindowManagement`, the interface that is used to create a window manager.

The code for this software is in the `zlux-app-manager` repository.

The interface for building an alternative window manager is in the `zlux-platform` repository.

Window Management acts upon Windows, which are visualizations of an instance of an application plug-in. Application plug-ins are plug-ins of the type "application", and therefore the Zowe Desktop operates around a collection of plug-ins.

Note: Other objects and frameworks that can be utilized by application plug-ins, but not related to window management, such as application-to-application communication, Logging, URI lookup, and Auth are not described here.

Loading and presenting application plug-ins

Upon loading the Zowe Desktop, a GET call is made to `/plugins?type=application`. The GET call returns a JSON list of all application plug-ins that are on the server, which can be accessed by the user. Application plug-ins can be composed of dataservices, web content, or both. Application plug-ins that have web content are presented in the Zowe Desktop UI.

The Zowe Desktop has a taskbar at the bottom of the page, where it displays each application plug-in as an icon with a description. The icon that is used, and the description that is presented are based on the application plug-in's `PluginDefinition`'s `webContent` attributes.

Plug-in management

Application plug-ins can gain insight into the environment in which they were spawned through the Plugin Manager. Use the Plugin Manager to determine whether a plug-in is present before you act upon the existence of that plug-in. When the Zowe Desktop is running, you can access the Plugin Manager through `RocketMVD.PluginManager`

The following are the functions you can use on the Plugin Manager:

- `getPlugin(pluginID: string)`
- Accepts a string of a unique plug-in ID, and returns the Plugin Definition Object (`DesktopPluginDefinition`) that is associated with it, if found.

Application management

Application plug-ins within a Window Manager are created and acted upon in part by an Application Manager. The Application Manager can facilitate communication between application plug-ins, but formal application-to-application communication should be performed by calls to the Dispatcher. The Application Manager is not normally directly accessible by application plug-ins, instead used by the Window Manager.

The following are functions of an Application Manager:

Function	Description
<code>spawnApplication(plugin: DesktopPluginDefinition, launchMetadata: any): Promise<MVDHosting.InstanceId>;</code>	Opens an application instance into the Window Manager, with or without context on what actions it should perform after creation.
<code>killApplication(plugin: ZLUX.Plugin, appId: MVDHosting.InstanceId): void;</code>	Removes an application instance from the Window Manager.
<code>showApplicationWindow(plugin: DesktopPluginDefinitionImpl): void;</code>	Makes an open application instance visible within the Window Manager.
<code>isApplicationRunning(plugin: DesktopPluginDefinitionImpl): boolean;</code>	Determines if any instances of the application are open in the Window Manager.

Windows and Viewports

When a user clicks an application plug-in's icon on the taskbar, an instance of the application plug-in is started and presented within a Viewport, which is encapsulated in a Window within the Zowe Desktop. Every instance of an application plug-in's web content within Zowe is given context and can listen on events about the Viewport and Window it exists within, regardless of whether the Window Manager implementation utilizes these constructs visually. It is possible to create a Window Manager that only displays one application plug-in at a time, or to have a drawer-and-panel UI rather than a true windowed UI.

When the Window is created, the application plug-in's web content is encapsulated dependent upon its framework type. The following are valid framework types:

- *"angular2"*: The web content is written in Angular, and packaged with Webpack. Application plug-in framework objects are given through @injectables and imports.
- *"iframe"*: The web content can be written using any framework, but is included through an iframe tag. Application plug-ins within an iframe can access framework objects through *parent.RocketMVD* and callbacks.

In the case of the Zowe Desktop, this framework-specific wrapping is handled by the Plugin Manager.

Viewport Manager

Viewports encapsulate an instance of an application plug-in's web content, but otherwise do not add to the UI (they do not present Chrome as a Window does). Each instance of an application plug-in is associated with a viewport, and operations to act upon a particular application plug-in instance should be done by specifying a viewport for an application plug-in, to differentiate which instance is the target of an action. Actions performed against viewports should be performed through the Viewport Manager.

The following are functions of the Viewport Manager:

Function	Description
<code>createViewport(providers: ResolvedReflectiveProvider[]): MVDHosting.ViewportId;</code>	Creates a viewport into which an application plug-in's webcontent can be embedded.
<code>registerViewport(viewportId: MVDHosting.ViewportId, instanceId: MVDHosting.InstanceId): void;</code>	Registers a previously created viewport to an application plug-in instance.
<code>destroyViewport(viewportId: MVDHosting.ViewportId): void;</code>	Removes a viewport from the Window Manager.
<code>getApplicationInstanceId(viewportId: MVDHosting.ViewportId): MVDHosting.InstanceId null;</code>	Returns the ID of an application plug-in's instance from within a viewport within the Window Manager.

Injection Manager

When you create Angular application plug-ins, they can use injectables to be informed of when an action occurs. iframe application plug-ins indirectly benefit from some of these hooks due to the wrapper acting upon them, but Angular application plug-ins have direct access.

The following topics describe injectables that application plug-ins can use.

Plug-in definition

```
@Inject(Angular2InjectionTokens.PLUGIN_DEFINITION) private pluginDefinition:
  ZLUX.ContainerPluginDefinition
```

Provides the plug-in definition that is associated with this application plug-in. This injectable can be used to gain context about the application plug-in. It can also be used by the application plug-in with other application plug-in framework objects to perform a contextual action.

Logger

```
@Inject(Angular2InjectionTokens.LOGGER) private logger: ZLUX.ComponentLogger
```

Provides a logger that is named after the application plug-in's plugin definition ID.

Launch Metadata

```
@Inject(Angular2InjectionTokens.LAUNCH_METADATA) private launchMetadata: any
```

If present, this variable requests the application plug-in instance to initialize with some context, rather than the default view.

Viewport Events

```
@Inject(Angular2InjectionTokens.VIEWPORT_EVENTS) private viewportEvents:  
  Angular2PluginViewportEvents
```

Presents hooks that can be subscribed to for event listening. Events include:

`resized: Subject<{width: number, height: number}>`

Fires when the viewport's size has changed.

Window Events

```
@Inject(Angular2InjectionTokens.WINDOW_ACTIONS) private windowActions:  
  Angular2PluginWindowActions
```

Presents hooks that can be subscribed to for event listening. The events include:

Event	Description
<code>maximized: Subject<void></code>	Fires when the Window is maximized.
<code>minimized: Subject<void></code>	Fires when the Window is minimized.
<code>restored: Subject<void></code>	Fires when the Window is restored from a minimized state.
<code>moved: Subject<{top: number, left: number}></code>	Fires when the Window is moved.
<code>resized: Subject<{width: number, height: number}></code>	Fires when the Window is resized.
<code>titleChanged: Subject<string></code>	Fires when the Window's title changes.

Window Actions

```
@Inject(Angular2InjectionTokens.WINDOW_ACTIONS) private windowActions:  
  Angular2PluginWindowActions
```

An application plug-in can request actions to be performed on the Window through the following:

Item	Description
<code>close(): void</code>	Closes the Window of the application plug-in instance.
<code>maximize(): void</code>	Maximizes the Window of the application plug-in instance.
<code>minimize(): void</code>	Minimizes the Window of the application plug-in instance.
<code>restore(): void</code>	Restores the Window of the application plug-in instance from a minimized state.
<code>setTitle(title: string):void</code>	Sets the title of the Window.
<code>setPosition(pos: {top: number, left: number, width: number, height: number}): void</code>	Sets the position of the Window on the page and the size of the window.

Item	Description
<code>spawnContextMenu(xPos: number, yPos: number, items: ContextMenuItem[]): void</code>	Opens a context menu on the application plug-in instance, which uses the Context Menu framework.
<code>registerCloseHandler(handler: () => Promise<void>): void</code>	Registers a handler, which is called when the Window and application plug-in instance are closed.

Configuration Dataservice

The Configuration Dataservice is an essential component of the zLUX framework, which acts as a JSON resource storage service, and is accessible externally by REST API and internally to the server by dataservices.

The Configuration Dataservice allows for saving preferences of applications, management of defaults and privileges within a zLUX ecosystem, and bootstrapping configuration of the server's dataservices.

The fundamental element of extensibility of the zLUX framework is a plug-in. The Configuration Dataservice works with data for plug-ins. Every resource that is stored in the Configuration Service is stored for a particular plug-in, and valid resources to be accessed are determined by the definition of each plug-in in how it uses the Configuration Dataservice.

The behavior of the Configuration Dataservice is dependent upon the Resource structure for a plug-in. Each plug-in lists the valid resources, and the administrators can set permissions for the users who can view or modify these resources.

Resource Scope

Data is stored within the Configuration Dataservice according to the selected *Scope*. The intent of *Scope* within the Dataservice is to facilitate company-wide administration and privilege management of zLUX data.

When a user requests a resource, the resource that is retrieved is an override or an aggregation of the broader scopes that encompass the *Scope* from which they are viewing the data.

When a user stores a resource, the resource is stored within a *Scope* but only if the user has access privilege to update within that *Scope*.

Scope is one of the following:

Product

Configuration defaults that come with the product. Cannot be modified.

Site

Data that can be used between multiple instances of the zLUX Server.

Instance

Data within an individual zLUX Server.

Group

Data that is shared between multiple users in a group.

User

Data for an individual user.

Note: While Authorization tuning can allow for settings such as GET from Instance to work without login, *User* and *Group* scope queries will be rejected if not logged in due to the requirement to pull resources from a specific user. Because of this, *User* and *Group* scopes will not be functional until the Security Framework is available.

Where *Product* is the broadest scope and *User* is the narrowest scope.

When you specify *Scope User*, the service manages configuration for your particular username, using the authentication of the session. This way, the *User* scope is always mapped to your current username.

Consider a case where a user wants to access preferences for their text editor. One way they could do this is to use the REST API to retrieve the settings resource from the *Instance* scope.

The *Instance* scope might contain editor defaults set by the administrator. But, if there are no defaults in *Instance*, then the data in *Group* and *User* would be checked.

Therefore, the data the user receives would be no broader than what is stored in the *Instance* scope, but might have only been the settings they saved within their own *User* scope (if the broader scopes do not have data for the resource).

Later, the user might want to save changes, and they try to save them in the *Instance* scope. Most likely, this action is rejected because of the preferences set by the administrator to disallow changes to the *Instance* scope by ordinary users.

REST API

When you reach the Configuration Service through a REST API, HTTP methods are used to perform the desired operation.

The HTTP URL scheme for the configuration dataservice is:

```
<Server>/plugins/com.rs.configjs/services/data/<plugin ID>/<Scope>/<resource>/  
<optional subresources>?<query>
```

Where the resources are one or more levels deep, using as many layers of subresources as needed.

Think of a resource as a collection of elements, or a directory. To access a single element, you must use the query parameter "name="

REST query parameters

Name (string)

Get or put a single element rather than a collection.

Recursive (boolean)

When performing a DELETE, specifies whether to delete subresources.

REST HTTP methods

Below is an explanation of each type of REST call.

Each API call includes an example request and response against a hypothetical application called the "code editor".

GET

```
GET /plugins/com.rs.configjs/services/data/<plugin>/<scope>/<resource>?  
name=<element>
```

- This returns JSON with the attribute "content" being a JSON resource that is the entire configuration that was requested. For example:

```
/plugins/com.rs.configjs/services/data/org.openmainframe.zowe.codeeditor/user/  
sessions/default?name=tabs
```

The parts of the URL are:

- Plugin: org.openmainframe.zowe.codeeditor
- Scope: user
- Resource: sessions

- Subresource: default
- Element = tabs

The response body is a JSON config:

```
{
  "_objectType" : "com.rs.config.resource",
  "_metadataVersion" : "1.1",
  "resource" : "org.openmainframe.zowe.codeeditor/USER/sessions/default",
  "contents" : {
    "_metadataVersion" : "1.1",
    "_objectType" : "org.openmainframe.zowe.codeeditor.sessions.tabs",
    "tabs" : [
      {
        "title" : "TSSPG.REXX.EXEC(ARCTEST2)",
        "filePath" : "TSSPG.REXX.EXEC(ARCTEST2)",
        "isDataset" : true
      },
      {
        "title" : ".profile",
        "filePath" : "/u/tsspg/.profile"
      }
    ]
  }
}
```

GET /plugins/com.rs.configjs/services/data/<plugin>/<scope>/<resource>

This returns JSON with the attribute content being a JSON object that has each attribute being another JSON object, which is a single configuration element.

GET /plugins/com.rs.configjs/services/data/<plugin>/<scope>/<resource>

(When subresources exist.)

This returns a listing of subresources that can, in turn, be queried.

PUT

PUT /plugins/com.rs.configjs/services/data/<plugin>/<scope>/<resource>?
name=<element>

Stores a single element (must be a JSON object {...}) within the requested scope, ignoring aggregation policies, depending on the user privilege. For example:

/plugins/com.rs.configjs/services/data/org.openmainframe.zowe.codeeditor/user/sessions/default?name=tabs

Body:

```
{
  "_metadataVersion" : "1.1",
  "_objectType" : "org.openmainframe.zowe.codeeditor.sessions.tabs",
  "tabs" : [
    {
      "title" : ".profile",
      "filePath" : "/u/tsspg/.profile"
    },
    {
      "title" : "TSSPG.REXX.EXEC(ARCTEST2)",
      "filePath" : "TSSPG.REXX.EXEC(ARCTEST2)",
      "isDataset" : true
    },
    {
      "title" : ".emacs",
      "filePath" : "/u/tsspg/.emacs"
    }
  ]
}
```

Response:

```
{
  "_objectType" : "com.rs.config.resourceUpdate",
  "_metadataVersion" : "1.1",
  "resource" : "org.openmainframe.zowe.codeeditor/USER/sessions/default",
  "result" : "Replaced item."
}
```

DELETE

DELETE /plugins/com.rs.configjs/services/data/<plugin>/<scope>/<resource>?
recursive=true

Deletes all files in all leaf resources below the resource specified.

DELETE /plugins/com.rs.configjs/services/data/<plugin>/<scope>/<resource>?
name=<element>

Deletes a single file in a leaf resource.

DELETE /plugins/com.rs.configjs/services/data/<plugin>/<scope>/<resource>

- Deletes all files in a leaf resource.
- Does not delete the directory on disk.

Administrative access and group

By means not discussed here, but instead handled by the server's authentication and authorization code, a user might be privileged to access or modify items that they do not own.

In the simplest case, it might mean that the user is able to do a PUT, POST, or DELETE to a level above *User*, such as *Instance*.

The more interesting case is in accessing another user's contents. In this case, the shape of the URL is different. Compare the following two commands:

GET /plugins/com.rs.configjs/services/data/<plugin>/user/<resource>

Gets the content for the current user.

GET /plugins/com.rs.configjs/services/data/<plugin>/users/<username>/<resource>

Gets the content for a specific user if authorized.

This is the same structure that is used for the *Group* scope. When requesting content from the *Group* scope, the user is checked to see if they are authorized to make the request for the specific group. For example:

GET /plugins/com.rs.configjs/services/data/<plugin>/group/<groupname>/
<resource>

Gets the content for the given group, if the user is authorized.

Application API

Retrieves and stores configuration information from specific scopes.

Note: This API should only be used for configuration administration user interfaces.

ZLUX.UriBroker.pluginConfigForScopeUri(pluginDefinition: ZLUX.Plugin, scope: string, resourcePath:string, resourceName:string): string;

A shortcut for the preceding method, and the preferred method when you are retrieving configuration information, is simply to "consume" it. It "asks" for configurations using the *User* scope, and allows the configuration service to decide which configuration information to retrieve and how to aggregate it. (See below on how the configuration service evaluates what to return for this type of request).

ZLUX.UriBroker.pluginConfigUri(pluginDefinition: ZLUX.Plugin, resourcePath:string, resourceName:string): string;

Internal and bootstrapping

Some dataservices within plug-ins can take configuration that affects their behavior. This configuration is stored within the Configuration Dataservice structure, but it is not accessible through the REST API.

Within the deploy directory of a Zowe installation, each plug-in might optionally have an `_internal` directory. An example of such a path is:

`deploy/instance/ZLUX/pluginStorage/<pluginName>/_internal`

Within each `_internal` directory, the following directories might exist:

- `services/<servicename>`: Configuration resources for the specific service.
- `plugin`: Configuration resources that are visible to all services in the plug-in.

The JSON contents within these directories are provided as Objects to dataservices through the `dataservice` context Object.

Plug-in definition

Because the Configuration Dataservices stores data on a per-plug-in basis, each plug-in must define their resource structure to make use of the Configuration Dataservice. The resource structure definition is included in the plug-in's `pluginDefinition.json` file.

For each resource and subresource, you can define an `aggregationPolicy` to control how the data of a broader scope alters the resource data that is returned to a user when requesting a resource from a narrower scope.

For example:

```
"configurationData": { //is a direct attribute of the pluginDefinition JSON
  "resources": { //always required
    "preferences": {
      "locationType": "relative", //this is the only option for now, but later absolute paths
may be accepted
      "aggregationPolicy": "override" //override and none for now, but more in the future
    },
    "sessions": { //the name at this level represents the name used within a URL, such as /
plugins/com.rs.configjs/services/data/org.openmainframe.zowe.codeeditor/user/sessions
      "aggregationPolicy": "none",
      "subResources": {
        "sessionName": {
          "variable": true, //if variable=true is present, the resource must be the only
one in that group but the name of the resource is substituted for the name given in the REST
request, so it represents more than one
          "aggregationPolicy": "none"
        }
      }
    }
  }
}
```

Aggregation policies

Aggregation policies determine how the Configuration Dataservice aggregates JSON objects from different Scopes together when a user requests a resource. If the user requests a resource from the *User* scope, the data from the User scope might replace or be merged with the data from a broader scope such as *Instance*, to make a combined resource object that is returned to the user.

Aggregation policies are defined by a plug-in developer in the plug-in's definition for the Configuration Service, as the attribute `aggregationPolicy` within a resource.

The following policies are currently implemented:

- **NONE**: If the Configuration Dataservice is called for *Scope User*, only user-saved settings are sent, unless there are no user-saved settings for the query, in which case the dataservice attempts to send data that is found at a broader scope.
- **OVERRIDE**: The Configuration Dataservice obtains data for the resource that is requested at the broadest level found, and joins the resource's properties from narrower scopes, overriding broader attributes with narrower ones, when found.

URI Broker

The URI Broker is an object in the application plug-in web framework, which facilitates calls to the zLUX Application Server by constructing URIs that use the context from the calling application plug-in.

Accessing the URI Broker

The URI Broker is accessible independent of other frameworks involved such as Angular, and is also accessible through iframe. This is because it is attached to a global when within the Zowe Desktop. For more information, see [Zowe Desktop and window management](#). Access the URI Broker through one of two locations:

Natively:

```
window.RocketMVD.uriBroker
```

In an iframe:

```
window.parent.RocketMVD.uriBroker
```

Functions

The URI Broker builds the following categories of URIs depending upon what the application plug-in is designed to call.

Accessing an application plug-in's dataservices

Dataservices can be based on HTTP (REST) or Websocket. For more information, see [zLUX dataservices](#).

HTTP Dataservice URI

```
pluginRESTUri(plugin:ZLUX.Plugin, serviceName: string, relativePath:string):  
string
```

Returns: A URI for making an HTTP service request.

Websocket Dataservice URI

```
pluginWSUri(plugin: ZLUX.Plugin, serviceName:string, relativePath:string):  
string
```

Returns: A URI for making a Websocket connection to the service.

Accessing application plug-in's configuration resources

Defaults and user storage might exist for an application plug-in such that they can be retrieved through the Configuration Dataservice.

There are different scopes and actions to take with this service, and therefore there are a few URIs that can be built:

Standard configuration access

```
pluginConfigUri(pluginDefinition: ZLUX.Plugin, resourcePath:string,  
resourceName?:string): string
```

Returns: A URI for accessing the requested resource under the user's storage.

Scoped configuration access

```
pluginConfigForScopeUri(pluginDefinition: ZLUX.Plugin, scope: string,  
resourcePath:string, resourceName?:string): string
```

Returns: A URI for accessing a specific scope for a given resource.

Accessing static content

Content under an application plug-in's web directory is static content accessible by a browser. This can be accessed through:

```
pluginResourceUri(pluginDefinition: ZLUX.Plugin, relativePath: string): string
```

Returns: A URI for getting static content.

For more information about the web directory, see [Application plug-in filesystem structure](#).

Accessing the application plug-in's root

Static content and services are accessed off of the root URI of an application plug-in. If there are other points that you must access on that application plug-in, you can get the root:

```
pluginRootUri(pluginDefinition: ZLUX.Plugin): string
```

Returns: A URI to the root of the application plug-in.

Server queries

A client can find different information about a server's configuration or the configuration as seen by the current user by accessing specific APIs.

Accessing a list of plug-ins

```
pluginListUri(pluginType: ZLUX.PluginType): string
```

Returns: A URI, which when accessed returns the list of existing plug-ins on the server by type, such as "Application" or "all".

Application-to-application communication

zLUX application plug-ins can opt-in to various application framework abilities, such as the ability to have a Logger, use of a URI builder utility, and more. One ability that is unique to a zLUX environment with multiple application plug-ins is the ability for one application plug-in to communicate with another. The application framework provides constructs that facilitate this ability. The constructs are: the Dispatcher, Actions, Recognizers, Registry, and the features that utilize them such as the framework's Context menu.

1. [Why use application-to-application communication?](#)
2. [Actions](#)
3. [Recognizers](#)
4. [Dispatcher](#)

Why use application-to-application communication?

When working with a computer, people often use multiple applications to accomplish a task, for example checking a dashboard before digging into a detailed program or checking email before opening a bank statement in a browser. In many environments, the relationship between one program and another is not well defined (you might open one program to learn of a situation, which you solve by opening another and typing or pasting in content). Or perhaps a hyperlink is provided or an attachment, which opens program by using a lookup table of which the program is the default for handling a certain file extension. The application framework attempts to solve this problem by creating structured messages that can be sent from one application plug-in to another. An application plug-in has a context of the information that it contains. You can use this context to invoke an action on another application plug-in that is better suited to handle some of the information discovered in the first application plug-in. Well-structured messages facilitate knowing what application plug-in is "right" to handle a situation, and explain in detail what that application plug-in should do. This way, rather than finding out that the attachment with the extension ".dat" was not meant for a text editor, but instead for an email client, one application plug-in might instead be able to invoke an action on an application plug-in, which can handle opening of an

email for the purpose of forwarding to others (a more specific task than can be explained with filename extensions).

Actions

To manage communication from one application plug-in to another, a specific structure is needed. In the application framework, the unit of application-to-application communication is an Action. The typescript definition of an Action is as follows:

```
export class Action implements ZLUX.Action {
  id: string; // id of action itself.
  i18nNameKey: string; // future proofing for I18N
  defaultName: string; // default name for display purposes, w/o I18N
  description: string;
  targetMode: ActionTargetMode;
  type: ActionType; // "launch", "message"
  targetPluginID: string;
  primaryArgument: any;

  constructor(id: string,
    defaultName: string,
    targetMode: ActionTargetMode,
    type: ActionType,
    targetPluginID: string,
    primaryArgument: any) {
    this.id = id;
    this.defaultName = defaultName;
    // proper name for ID/type
    this.targetPluginID = targetPluginID;
    this.targetMode = targetMode;
    this.type = type;
    this.primaryArgument = primaryArgument;
  }

  getDefaultName(): string {
    return this.defaultName;
  }
}
```

An Action has a specific structure of data that is passed, to be filled in with the context at runtime, and a specific target to receive the data. The Action is dispatched to the target in one of several modes, for example: to target a specific instance of an application plug-in, an instance, or to create a new instance. The Action can be less detailed than a message. It can be a request to minimize, maximize, close, launch, and more. Finally, all of this information is related to a unique ID and localization string such that it can be managed by the framework.

Action target modes

When you request an Action on an application plug-in, the behavior is dependent on the instance of the application plug-in you are targeting. You can instruct the framework how to target the application plug-in with a target mode from the ActionTargetMode enum:

```
export enum ActionTargetMode {
  PluginCreate, // require pluginType
  PluginFindUniqueOrCreate, // required AppInstance/ID
  PluginFindAnyOrCreate, // plugin type
  //TODO PluginFindAnyOrFail
  System, // something that is always present
}
```

Action types

The application framework performs different operations on application plug-ins depending on the type of an Action. The behavior can be quite different, from simple messaging to requesting that an application plug-in be minimized. The types are defined by an enum:

```
export enum ActionType {
  Launch, // essentially do nothing after target mode
  Focus, // bring to fore, but nothing else
  Route, // sub-navigate or "route" in target
  Message, // "onMessage" style event to plugin
}
```

```

Method,                // Method call on instance, more strongly typed
Minimize,
Maximize,
Close,                  // may need to call a "close handler"
}

```

Loading actions

Actions can be created dynamically at runtime, or saved and loaded by the system at login.

Dynamically

You can create Actions by calling the following Dispatcher method: `makeAction(id: string, defaultName: string, targetMode: ActionTargetMode, type: ActionType, targetPluginID: string, primaryArgument: any):Action`

Saved on system

Actions can be stored in JSON files that are loaded at login. The JSON structure is as follows:

```

{
  "actions": [
    {
      "id": "org.zowe.explorer.openmember",
      "defaultName": "Edit PDS in MVS Explorer",
      "type": "Launch",
      "targetMode": "PluginCreate",
      "targetId": "org.zowe.explorer",
      "arg": {
        "type": "edit_pds",
        "pds": {
          "op": "deref",
          "source": "event",
          "path": [
            "full_path"
          ]
        }
      }
    }
  ]
}

```

Recognizers

Actions are meant to be invoked when certain conditions are met. For example, you do not need to open a messaging window if you have no one to message. Recognizers are objects within the application framework that use the context that the application plug-in provides to determine if there is a condition for which it makes sense to execute an Action. Each recognizer has statements about what condition to recognize, and upon that statement being met, which Action can be executed at that time. The invocation of the Action is not handled by the Recognizer; it simply detects that an Action can be taken.

Recognition clauses

Recognizers associate a clause of recognition with an action, as you can see from the following class:

```

export class RecognitionRule {
  predicate:RecognitionClause;
  actionID:string;

  constructor(predicate:RecognitionClause, actionID:string){
    this.predicate = predicate;
    this.actionID = actionID;
  }
}

```

A clause, in turn, is associated with an operation, and the subclauses upon which the operation acts. The following operations are supported:

```

export enum RecognitionOp {
  AND,
  OR,
}

```

```

NOT,
PROPERTY_EQ,
SOURCE_PLUGIN_TYPE, // syntactic sugar
MIME_TYPE, // ditto
}

```

Loading Recognizers at runtime

You can add a Recognizer to the application plug-in environment in one of two ways: by loading from Recognizers saved on the system, or by adding them dynamically.

Dynamically

You can call the Dispatcher method, `addRecognizer(predicate:RecognitionClause, actionID:string):void`

Saved on system

Recognizers can be stored in JSON files that are loaded at login. The JSON structure is as follows:

```

{
  "recognizers": [
    {
      "id": "<actionID>",
      "clause": {
        <clause>
      }
    }
  ]
}

```

clause can take on one of two shapes:

```
"prop": ["<keyString>", "<valueString>"]
```

Or,

```

"op": "<op enum as string>",
"args": [
  {<clause>}
]

```

Where this one can again, have subclauses.

Recognizer example

Recognizers can be simple or complex. The following is an example to illustrate the mechanism:

```

{
  "recognizers": [
    {
      "id": "org.zowe.explorer.openmember",
      "clause": {
        "op": "AND",
        "args": [
          {"prop": ["sourcePluginID", "com.rs.mvd.tn3270"]}, {"prop": ["screenID", "ISRUDSM"]}
        ]
      }
    }
  ]
}

```

In this case, the Recognizer detects whether it is possible to run the `org.zowe.explorer.openmember` Action when the TN3270 Terminal application plug-in is on the screen ISRUDSM (an ISPF panel for browsing PDS members).

Dispatcher

The dispatcher is a core component of the application framework that is accessible through the Global ZLUX Object at runtime. The Dispatcher interprets Recognizers and Actions that are added to it at

runtime. You can register Actions and Recognizers on it, and later, invoke an Action through it. The dispatcher handles how the Action's effects should be carried out, acting in combination with the Window Manager and application plug-ins themselves to provide a channel of communication.

Registry

The Registry is a core component of the application framework, which is accessible through the Global ZLUX Object at runtime. It contains information about which application plug-ins are present in the environment, and the abilities of each application plug-in. This is important to application-to-application communication, because a target might not be a specific application plug-in, but rather an application plug-in of a specific category, or with a specific featureset, or capable of responding to the type of Action requested.

Pulling it all together in an example

The standard way to make use of application-to-application communication is by having Actions and Recognizers that are saved on the system. Actions and Recognizers are loaded at login, and then later, through a form of automation or by a user action, Recognizers can be polled to determine if there is an Action that can be executed. All of this is handled by the Dispatcher, but the description of the behavior lies in the Action and Recognizer that are used. In the Action and Recognizer descriptions above, there are two JSON definitions: One is a Recognizer that recognizes when the Terminal application plug-in is in a certain state, and another is an Action that instructs the MVS Explorer to load a PDS member for editing. When you put the two together, a practical application is that you can launch the MVS Explorer to edit a PDS member that you have selected within the Terminal application plug-in.

Error reporting UI

The zLUX Widgets repository contains shared widget-like components of the Zowe Desktop, including Button, Checkbox, Paginator, various pop-ups, and others. To maintain consistency in desktop styling across all applications, use, reuse, and customize existing widgets to suit the purpose of the application's function and look.

Ideally, a program should have little to no logic errors. Once in a while a few occur, but more commonly an error occurs from misconfigured user settings. A user might request an action or command that requires certain prerequisites, for example: a proper ZSS-Server configuration. If the program or method fails, the program should notify the user through the UI about the error and how to fix it. For the purposes of this discussion, we will use the Workflow application plug-in in the `zlux-workflow` repository.

ZluxPopupManagerService

The `ZluxPopupManagerService` is a standard popup widget that can, through its `reportError()` method, be used to display errors with attributes that specify the title or error code, severity, text, whether it should block the user from proceeding, whether it should output to the logger, and other options you want to add to the error dialog. `ZluxPopupManagerService` uses both `ZluxErrorSeverity` and `ErrorReportStruct`.

```
`export declare class ZluxPopupManagerService {`  
  eventsSubject: any;  
  listeners: any;  
  events: any;  
  logger: any;  
  constructor();  
  setLogger(logger: any): void;  
  on(name: any, listener: any): void;  
  broadcast(name: any, ...args: any[]): void;  
  processButtons(buttons: any[]): any[];  
  block(): void;  
  unblock(): void;  
  getLoggerSeverity(severity: ZluxErrorSeverity): any;  
  reportError(severity: ZluxErrorSeverity, title: string, text: string, options?: any):  
  Rx.Observable<any>;
```

```
`}`
```

ZluxErrorSeverity

ZluxErrorSeverity classifies the type of report. Under the popup-manager, there are the following types: error, warning, and information. Each type has its own visual style. To accurately indicate the type of issue to the user, the error or pop-up should be classified accordingly.

```
`export declare enum ZluxErrorSeverity {`  
    ERROR = "error",  
    WARNING = "warning",  
    INFO = "info",  
`}`
```

ErrorReportStruct

ErrorReportStruct contains the main interface that brings the specified parameters of reportError() together.

```
`export interface ErrorReportStruct {`  
    severity: string;  
    modal: boolean;  
    text: string;  
    title: string;  
    buttons: string[];  
`}`
```

Implementation

Import ZluxPopupManagerService and ZluxErrorSeverity from widgets. If you are using additional services with your error prompt, import those too (for example, LoggerService to print to the logger or GlobalVeilService to create a visible semi-transparent gray veil over the program and pause background tasks). Here, widgets is imported from node_modules\@zlux\ so you must ensure zLUX widgets is used in your package-lock.json or package.json and you have run npm install.

```
import { ZluxPopupManagerService, ZluxErrorSeverity } from '@zlux/widgets';
```

Declaration

Create a member variable within the constructor of the class you want to use it for. For example, in the Workflow application plug-in under \zlux-workflow\src\app\app\zosmf-server-config.component.ts is a ZosmfServerConfigComponent class with the pop-up manager service variable. To automatically report the error to the console, you must set a logger.

```
`export class ZosmfServerConfigComponent {`  
    constructor(  
        private popupManager: ZluxPopupManagerService, )  
    { popupManager.setLogger(logger); } //Optional  
`}`
```

Usage

Now that you have declared your variable within the scope of your program's class, you are ready to use the method. The following example describes an instance of the reload() method in Workflow that catches an error when the program attempts to retrieve a configuration from a configService and set it to the program's this.config. This method fails when the user has a faulty zss-Server configuration and the error is caught and then sent to the class' popupManager variable from the constructor above.

```
`reload(): void {`  
    this.globalVeilService.showVeil();  
    this.configService  
        .getConfig()
```

```

.then(config => (this.config = config))
.then(_ => setTimeout(() => this.test(), 0))
.then(_ => this.globalVeilService.hideVeil())
.catch(err => {
  this.globalVeilService.hideVeil()
  let errorTitle: string = "Error";
  let errorMessage: string = "Server configuration not found. Please check your zss
server.";
  const options = {
    blocking: true
  };
  this.popupManager.reportError(ZluxErrorSeverity.ERROR, errorTitle.toString()+":
"+err.status.toString(), errorMessage+"\n"+err.toString(), options);
});
}

```

Here, the `errorMessage` clearly describes the error with a small degree of ambiguity as to account for all types of errors that might occur from that method. The specifics of the error are then generated dynamically and are printed with the `err.toString()`, which contains the more specific information that is used to pinpoint the problem. The `this.popupManager.report()` method triggers the error prompt to display. The error severity is set with `ZluxErrorSeverity.ERROR` and the `err.status.toString()` describes the status of the error (often classified by a code, for example: 404). The optional parameters in `options` specify that this error will block the user from interacting with the application plug-in until the error is closed or it until goes away on its own. `globalVeilService` is optional and is used to create a gray veil on the outside of the program when the error is caused. You must import `globalVeilService` separately (see the `zlux-workflow` repository for more information).

HTML

The final step is to have the recently created error dialog display in the application plug-in. If you do `this.popupManager.report()` without adding the component to your template, the error will not be displayed. Navigate to your component's `.html` file. On the Workflow application plug-in, this file will be in `\zlux-workflow\src\app\app\zosmf-server-config.component.html` and the only item left is to add the popup manager component alongside your other classes.

```
<zlux-popup-manager></zlux-popup-manager>
```

So now when the error is called, the new UI element should resemble the following:

The order in which you place the pop-up manager determines how the error dialog will overlap in your UI. If you want the error dialog to overlap other UI elements, place it at the end of the `.html` file. You can also create custom styling through a CSS template, and add it within the scope of your application plug-in.

Logging utility

The `zlux-shared` repository provides a logging utility for use by dataservices and web content for an application plug-in.

Logging objects

The logging utility is based on the following objects:

- **Component Loggers:** Objects that log messages for an individual component of the environment, such as a REST API for an application plug-in or to log user access.
- **Destinations:** Objects that are called when a component logger requests a message to be logged. Destinations determine how something is logged, for example, to a file or to a console, and what formatting is applied.
- **Logger:** Central logging object, which can spawn component loggers and attach destinations.

Logger IDs

Because Zowe application plug-ins have unique identifiers, both dataservices and an application plug-in's web content are provided with a component logger that knows this unique ID such that messages that are logged can be prefixed with the ID. With the association of logging to IDs, you can control verbosity of logs by setting log verbosity by ID.

Accessing logger objects

Logger

The core logger object is attached as a global for low-level access.

App Server

NodeJS uses `global` as its global object, so the logger is attached to:
`global.COM_RS_COMMON_LOGGER`

Web

Browsers use `window` as the global object, so the logger is attached to:
`window.COM_RS_COMMON_LOGGER`

Component logger

Component loggers are created from the core logger object, but when working with an application plug-in, allow the application plug-in framework to create these loggers for you. An application plug-in's component logger is presented to dataservices or web content as follows.

App Server

See **Router Dataservice Context** in the topic [zLUX dataservices](#).

Web

(Angular App Instance Injectable). See **Logger** in [Zowe Desktop and window management](#).

Logger API

The following constants and functions are available on the central logging object.

Attribute	Type	Description	Arguments
<code>makeComponentLogger</code>	function	Creates a component logger - Automatically done by the application framework for dataservices and web content	<code>componentIDString</code>

Attribute	Type	Description	Arguments
setLogLevelForComponentName	function	Sets the verbosity of an existing component logger	componentIDString, logLevel

Component Logger API

The following constants and functions are available to each component logger.

Attribute	Type	Description	Arguments
SEVERE	const	Is a const for logLevel	
WARNING	const	Is a const for logLevel	
INFO	const	Is a const for logLevel	
FINE	const	Is a const for logLevel	
FINER	const	Is a const for logLevel	
FINEST	const	Is a const for logLevel	
log	function	Used to write a log, specifying the log level	logLevel, messageString
severe	function	Used to write a SEVERE log.	messageString
warn	function	Used to write a WARNING log.	messageString
info	function	Used to write an INFO log.	messageString
debug	function	Used to write a FINE log.	messageString
makeSublogger	function	Creates a new component logger with an ID appended by the string given	componentNameSuffix

Log Levels

An enum, `LogLevel`, exists for specifying the verbosity level of a logger. The mapping is:

Level	Number
SEVERE	0
WARNING	1
INFO	2
FINE	3
FINER	4
FINEST	5

Note: The default log level for a logger is **INFO**.

Logging verbosity

Using the component logger API, loggers can dictate at which level of verbosity a log message should be visible. You can configure the server or client to show more or less verbose messages by using the core logger's API objects.

Example: You want to set the verbosity of the org.zowe.foo application plug-in's dataservice, bar to show debugging information.

```
logger.setLogLevelForComponentName('org.zowe.foo.bar', LogLevel.DEBUG)
```

Configuring logging verbosity

The application plug-in framework provides ways to specify what component loggers you would like to set default verbosity for, such that you can easily turn logging on or off.

Server startup logging configuration

The server configuration file allows for specification of default log levels, as a top-level attribute `logLevel`, which takes key-value pairs where the key is a regex pattern for component IDs, and the value is an integer for the log levels.

For example:

```
"logLevel": {
  "com.rs.configjs.data.access": 2,
  //the string given is a regex pattern string, so .* at the end here will cover that service
  //and its subloggers.
  "com.rs.myplugin.myservice.*": 4
  //
  // '_' char reserved, and '_' at beginning reserved for server. Just as we reserve
  // '_internal' for plugin config data for config service.
  // _unp = universal node proxy core logging
  // "_unp.dsauth": 2
},
```

For more information about the server configuration file, see [Zowe Application Framework \(zLUX\) configuration](#).

Chapter 6. Extending Zowe CLI

You can install plug-ins to extend the capabilities of Zowe CLI.

Plug-ins CLI to third-party applications are also available, such as Visual Studio Code Extension for Zowe (powered by Zowe CLI).

Plug-ins add functionality to the product in the form of new command groups, actions, objects, and options.

Important! Plug-ins can gain control of your CLI application legitimately during the execution of every command. Install third-party plug-ins at your own risk. We make no warranties regarding the use of third-party plug-ins.

Note: For information about how to install, update, and validate a plug-in, see [Installing Plug-ins](#).

The following plug-ins are available:

CA Brightside Plug-in for IBM® CICS®

The Zowe CLI Plug-in for IBM CICS lets you extend Zowe CLI to interact with CICS programs and transactions. The plug-in uses the IBM CICS® Management Client Interface (CMCI) API to achieve the interaction with CICS. For more information, see CICS management client interface on the IBM Knowledge Center.

For more information, see [CA Brightside Plug-in for IBM CICS](#).

VSCode Extension for Zowe

The Visual Studio Code (VSCode) Extension for Zowe lets you interact with data sets that are stored on IBM z/OS mainframe. Install the extension directly to [VSCode](#) to enable the extension within the GUI. You can explore data sets, view their contents, make changes, and upload the changes to the mainframe. For some users, it can be more convenient to interact with data sets through a GUI rather than using command-line interfaces or 3270 emulators. The extension is powered by Zowe CLI.

For more information, see [VSCode Extension for Zowe](#).

Installing plug-ins

Use commands in the `plugins` command group to install and manage plug-ins for Zowe CLI.

Important! Plug-ins can gain control of your CLI application legitimately during the execution of every command. Install third-party plug-ins at your own risk. We make no warranties regarding the use of third-party plug-ins.

You can install the following plug-ins: - **Zowe CLI Plug-in for IBM CICS** Use `@brightside/cics` in your command syntax to install, update, and validate the plug-in.

Setting the registry

If you installed Zowe CLI from the `zowe-cli-bundle.zip` distributed with the Zowe PAX media, proceed to the [Install step](#).

If you installed Zowe CLI from a registry, confirm that NPM is set to target the registry by issuing the following command:

```
npm config set @brightside:registry https://api.bintray.com/npm/ca/brightside
```

Meeting the prerequisites

Ensure that you meet the prerequisites for a plug-in before you install the plug-in to Zowe CLI. For documentation related to each plug-in, see [Extending Zowe CLI](#).

Installing plug-ins

Issue an `install` command to install plug-ins to Zowe CLI. The `install` command contains the following syntax:

```
zowe plugins install [plugin...] [--registry <registry>]
```

Important! On Windows, you must run as an Administrator to install the product and plug-ins.

- **[plugin...]** (Optional) Specifies the name of a plug-in, an npm package, or a pointer to a (local or remote) URL. When you do not specify a plug-in version, the command installs the latest plug-in version and specifies the prefix that is stored in npm save-prefix. For more information, see [npm save prefix](#). For more information about npm semantic versioning, see [npm semver](#). Optionally, you can specify a specific version of a plug-in to install. For example, `zowe plugin install pluginName@^1.0.0`.

Tip: You can install multiple plug-ins with one command. For example, issue `zowe plugin install plugin1 plugin2 plugin3`

- **[--registry <registry>]** (Optional) Specifies a registry URL from which to install a plug-in when you do not use `npm config set` to set the registry initially.

Examples: Install plug-ins

- The following example illustrates the syntax to use to install a plug-in that is distributed with the `zowe-cli-bundle.zip`. If you are using `zowe-cli-bundle.zip`, issue the following command for each plug-in .tgz file:

```
zowe plugins install ./zowe-cli-cics-1.0.0-next.20180531.tgz
```

- The following example illustrates the syntax to use to install a plug-in that is named "my-plugin" from a specified registry:

```
zowe plugins install @brightside/my-plugin
```

- The following example illustrates the syntax to use to install a specific version of "my-plugins"

```
zowe plugins install @brightside/my-plugin@"^1.2.3"
```

Validating plug-ins

Issue the plug-in validation command to run tests against all plug-ins (or against a plug-in that you specify) to verify that the plug-ins integrate properly with Zowe CLI. The tests confirm that the plug-in does not conflict with existing command groups in the base application. The command response provides you with details or error messages about how the plug-ins integrate with Zowe CLI.

Perform validation after you install the plug-ins to help ensure that it integrates with Zowe CLI.

The `validate` command has the following syntax:

```
zowe plugins validate [plugin]
```

- **[plugin]** (Optional) Specifies the name of the plug-in that you want to validate. If you do not specify a plug-in name, the command validates all installed plug-ins. The name of the plug-in is not always the same as the name of the NPM package.

Examples: Validate plug-ins

- The following example illustrates the syntax to use to validate a specified installed plug-in:

```
zowe plugins validate @brightside/my-plugin
```

- The following example illustrates the syntax to use to validate all installed plug-ins:

```
zowe plugins validate
```

Updating plug-ins

Issue the update command to install the latest version or a specific version of a plug-in that you installed previously. The update command has the following syntax:

```
zowe plugins update [plugin...] [--registry <registry>]
```

- **[plugin...]**

Specifies the name of an installed plug-in that you want to update. The name of the plug-in is not always the same as the name of the NPM package. You can use npm semantic versioning to specify a plug-in version to which to update. For more information, see [npm semver](#).

- **[--registry <registry>]**

(Optional) Specifies a registry URL that is different from the registry URL of the original installation.

Examples: Update plug-ins

- The following example illustrates the syntax to use to update an installed plug-in to the latest version:

```
zowe plugins update @brightside/my-plugin@latest
```

- The following example illustrates the syntax to use to update a plug-in to a specific version:

```
zowe plugins update @brightside/my-plugin@"^1.2.3"
```

Uninstalling plug-ins

Issue the uninstall command to uninstall plug-ins from a base application. After the uninstall process completes successfully, the product no longer contains the plug-in configuration.

Tip: The command is equivalent to using [npm uninstall](#) to uninstall a package.

The uninstall command contains the following syntax:

```
zowe plugins uninstall [plugin]
```

- **[plugin]** Specifies the plug-in name to uninstall.

Example: Uninstall plug-ins

- The following example illustrates the syntax to use to uninstall a plug-in:

```
zowe plugins uninstall @brightside/my-plugin
```

Zowe CLI Plug-in for IBM CICS

The Zowe CLI Plug-in for IBM® CICS® lets you extend Zowe CLI to interact with CICS programs and transactions. The plug-in uses the IBM CICS® Management Client Interface (CMCI) API to achieve the interaction with CICS. For more information, see [CICS management client interface](#) on the IBM Knowledge Center.

- [Use Cases](#)
- [Prerequisites](#)

- [Installing](#)
- [Setting up profiles](#)
- [Commands](#)

Use cases

As an application developer, you can use Zowe CLI Plug-in for IBM CICS to perform the following tasks:

- Deploy code changes to CICS applications that were developed with COBOL.
- Deploy changes to CICS regions for testing or delivery. See the [define command](#) for an example of how you can define programs to CICS to assist with testing and delivery.
- Automate CICS interaction steps in your CI/CD pipeline with Jenkins Automation Server or TravisCI.
- Deploy build artifacts to CICS regions.
- Alter, copy, define, delete, discard, and install CICS resources and resource definitions.

Prerequisites

Before you install the plug-in, meet the following prerequisites:

- [Install Zowe CLI](#) on your PC.
- Ensure that [IBM CICS Transaction Server v5.2](#) or later is installed and running in your mainframe environment.
- Ensure that [IBM CICS Management Client Interface \(CMCI\)](#) is configured and running in your CICS region.

Installing

Use one of the two following methods that you can use to install the Zowe CLI Plug-in for IBM CICS:

- [Installing from online registry](#)
- [Installing from local package](#)

Note: For more information about how to install multiple plug-ins, update to a specific version of a plug-ins, and install from specific registries, see [Install Plug-ins](#).

Installing from online registry

To install Zowe CLI from an online registry, complete the following steps:

1. Set your npm registry if you did not already do so when you installed Zowe CLI. Issue the following command:

```
npm config set @brightside:registry https://api.bintray.com/npm/ca/brightside
```

2. Open a command line window and issue the following command:

```
zowe plugins install @brightside/cics@next
```

Important! On Windows, you must run as an Administrator to install the product and plug-ins.

3. (Optional) After the command execution completes, issue the following command to validate that the installation completed successfully.

```
zowe plugins validate cics
```

Successful validation of the IBM CICS plug-in returns the response: Successfully validated.

Installing from local package

If you downloaded the Zowe PAX file and extracted the `zowe-cli-bundle.zip` package, complete the following steps to install the Zowe CLI Plug-in for CICS:

1. Open a command line window and change the local directory where you extracted the `zowe-cli-bundle.zip` file. If you do not have the `zowe-cli-bundle.zip` file, see the topic [Install Zowe CLI from local package](#) for information about how to obtain and extract it.
2. Issue the following command to install the plug-in:

```
zowe plugins install zowe-cli-cics-<VERSION_NUMBER>.tgz
```

- **<VERSION_NUMBER>**

The version of Zowe CLI Plug-in for CICS that you want to install from the package. The following is an example of a full package name for the plug-in: `zowe-core-2.0.0-next.201810161407.tgz`

Important! On Windows, you must run as an Administrator to install the product and plug-ins.

1. (Optional) After the command execution completes, issue the following command to validate that the installation completed successfully.

```
zowe plugins validate @brightside/cics
```

Successful validation of the CICS plug-in returns the response: `Successfully validated`. You can safely ignore `*** Warning: messages related to Imperative CLI Framework`.

Setting up profiles

A `cics` profile is required to issue commands in the CICS group that interact with CICS regions. The `cics` profile contains your host, port, username, and password for the IBM CMCI server of your choice. You can create multiple profiles and switch between them as needed.

Issue the following command to create a `cics` profile:

```
zowe profiles create cics <profile name> -H <host> -P <port> -u <user> -p <password>
```

Note: For more information about the ``` syntax, actions, and options, for `aprofiles create`` command, open Zowe CLI and issue the following command:

```
zowe profiles create cics -h
```

The result of the command displays as a success or failure message. You can use your profile when you issue commands in the `cics` command group.

Commands

The Zowe CLI Plug-in for IBM CICS adds the following commands to Zowe CLI:

- [Defining resources to CICS](#)
- [Deleting CICS resources](#)
- [Discarding CICS resources](#)
- [Getting CICS resources](#)
- [Installing resources to CICS](#)
- [Refreshing CICS programs](#)

Defining resources to CICS

The `define` command lets you define programs and transactions to CICS so that you can deploy and test the changes to your CICS application. To display a list of possible objects and options, issue the following command:

```
zowe cics define -h
```

Example:

Define a program named myProgram to the region named myRegion in the CICS system definition (CSD) group myGroup:

```
zowe cics define program myProgram myGroup --region-name myRegion
```

Deleting CICS resources

The delete command lets you delete previously defined CICS programs or transactions to help you deploy and test the changes to your CICS application. To display a list of possible objects and options, issue the following command:

```
zowe cics delete -h
```

Example:

Delete a program named PGM123 from the CICS region named MYREGION:

```
zowe cics delete program PGM123 --region-name MYREGION
```

Discarding CICS resources

The discard command lets you remove existing CICS program or transaction definitions to help you deploy and test the changes to your CICS application. To display a list of possible objects and options, issue the following command:

```
zowe cics discard -h
```

Example:

Discard a program named PGM123 from the CICS region named MYREGION:

```
zowe cics discard program PGM123 --region-name MYREGION
```

Getting CICS resources

The get command lets you get a list of programs and transactions that are installed in your CICS region so that you can determine if they were installed successfully and defined properly. To display a list of objects and options, issue the following command:

```
zowe cics get -h
```

Example:

Return a list of program resources from a CICS region named MYREGION:

```
zowe cics get resource CICSProgram --region-name MYREGION
```

Installing resources to CICS

The install command lets you install resources, such as programs and transactions, to a CICS region so that you can deploy and test the changes to your CICS application. To display a list of possible objects and options, issue the following command:

```
zowe cics install -h
```

Example:

Install a transaction named TRN1 to the region named MYREGION in the CSD group named MYGRP:

```
zowe cics install transaction TRN1 MYGRP --region-name MYREGION
```

Refreshing CICS programs

The refresh command lets you refresh changes to a CICS program so that you can deploy and test the changes to your CICS application. To display a list of objects and options, issue the following command:

```
zowe cics refresh -h
```

Example:

Refresh a program named PGM123 from the region named MYREGION:

```
zowe cics refresh PGM123 --region-name MYREGION
```
